Introduction to Plasma Theory

Dwight R. Nicholson

University of Iowa
To my wife Jane and my parents Forrest and Johanna
The purpose of this book is to teach the basic theoretical principles of plasma physics. It is not intended to be an encyclopedia of results and techniques. Nor is it intended to be used primarily as a reference book. It is intended to develop the basic techniques of plasma physics from the beginning, namely, from Maxwell’s equations and Newton’s law of motion. Absolutely no previous knowledge of plasma physics is assumed. Although the book is primarily intended for a one year course at the first or second year graduate level, it can also be used for a one or two semester course at the junior or senior undergraduate level. Such an undergraduate course would make use of that half of the book which assumes a knowledge only of undergraduate electricity and magnetism. The other half of the book, suitable for the graduate level, requires familiarity with complex variables, Fourier transformation, and the Dirac delta function.

The book is organized in a logical fashion. Although this is not the standard organization of an introductory course in plasma physics, I have found that students at the graduate level respond well to this organization. After the introductory material of Chapters 1 and 2 (single particle motion), the exact theories of Chapters 3 to 5 (Klimontovich and Liouville equations), which are equivalent to Maxwell’s equations plus Newton’s law of motion, are replaced via approximations by the Vlasov equation of Chapter 6. Further approximations lead to the fluid theory (Chapter 7) and magnetohydrodynamic theory (Chapter 8). The book concludes with two chapters on discrete particle effects (Chapter 9) and weak turbulence theory (Chapter 10). Chapter 6, and Chapters 7 and 8, are meant to be self-contained, so that the book can easily be used by instructors who wish the standard organization. Thus, the introductory material of Chapters 1 and 2 can be immediately followed by Chapters 7 and 8. This would be enough material for a
one semester undergraduate course, while the first half of a two semester graduate
course could continue with Chapter 6 on Vlasov theory, followed in the second
semester by Chapters 3 to 5 on kinetic theory and then by Chapters 9 and 10.

It is a pleasure to acknowledge the help of many individuals in writing this
book. My views on plasma physics have been shaped over the years by dozens of
plasma physicists, especially Allan N. Kaufman and Martin V. Goldman. The
students in graduate plasma physics courses at the University of Colorado and the
University of Iowa have contributed many useful suggestions (Sun Guo-Zheng
deserves special mention). The manuscript was professionally typed and edited by
Alice Conwell Shank, Gail Maxwell, Susan D. Imhoff, and Janet R. Kephart. The
figures were skillfully drafted by John R. Birkbeck, Jr. and Jeana K. Wonderlich.
The preparation of this book was supported by the University of Colorado, the
University of Iowa, the United States Department of Energy, the United States
National Aeronautics and Space Administration, and the United States National
Science Foundation.

INDEX 286
1.1 INTRODUCTION

A plasma is a gas of charged particles, in which the potential energy of a typical particle due to its nearest neighbor is much smaller than its kinetic energy. The plasma state is the fourth state of matter: heating a solid makes a liquid, heating a liquid makes a gas, heating a gas makes a plasma. (Compare the ancient Greeks’ earth, water, air, and fire.) The word plasma comes from the Greek plásma, meaning “something formed or molded.” It was introduced to describe ionized gases by Tonks and Langmuir [1]. More than 99% of the known universe is in the plasma state. (Note that our definition excludes certain configurations such as the electron gas in a metal and so-called “strongly coupled” plasmas which are found, for example, near the surface of the sun. These need to be treated by techniques other than those found in this book.)

In this book, we shall always consider plasma having roughly equal numbers of singly charged ions (+e) and electrons (−e), each with average density $n_0$ (particles per cubic centimeter). In nature many plasmas have more than two species of charged particles, and many ions have more than one electron missing. It is easy to generalize the results of this book to such plasmas.

EXERCISE Name a well-known proposed source of energy that involves plasma with more than one species of ion.

1.2 DEBYE SHIELDING

In a plasma we have many charged particles flying around at high speeds. Consider a special test particle of charge $q_T > 0$ and infinite mass, located at the origin of a
three-dimensional coordinate system containing an infinite, uniform plasma. The test charge repels all other ions, and attracts all electrons. Thus, around our test charge the electron density \( n_e \) increases and the ion density decreases. The test ion gathers a shielding cloud that tends to cancel its own charge (Fig. 1.1).

Consider Poisson’s equation relating the electric potential \( \varphi \) to the charge density \( \rho \) due to electrons, ions, and test charge,

\[
\nabla^2 \varphi = -4\pi \rho = 4\pi e (n_e - n_i) - 4\pi q_T \delta(r)
\]

(1.1)

where \( \delta(r) \equiv \delta(x)\delta(y)\delta(z) \) is the product of three Dirac delta functions. After the introduction of the test charge, we wait for a long enough time that the electrons with temperature \( T_e \) have come to thermal equilibrium with themselves, and the ions with temperature \( T_i \) have come to thermal equilibrium with themselves, but not so long that the electrons and ions have come to thermal equilibrium with each other at the same temperature (see Section 1.6). Then equilibrium statistical mechanics predicts that

\[
n_e = n_0 \exp \left( \frac{e\varphi}{T_e} \right), \quad n_i = n_0 \exp \left( \frac{-e\varphi}{T_i} \right)
\]

(1.2)

where each density becomes \( n_0 \) at large distances from the test charge where the potential vanishes. Boltzmann’s constant is absorbed into the temperatures \( T_e \) and \( T_i \), which have units of energy and are measured in units of electron-volts (eV).

Assuming that \( e\varphi/T_e \ll 1 \) and \( e\varphi/T_i \ll 1 \), we expand the exponents in (1.2) and write (1.1) away from \( r = 0 \) as

\[
\nabla^2 \varphi = \frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{d\varphi}{dr} \right) = 4\pi n_0 e^2 \left( \frac{1}{T_e} + \frac{1}{T_i} \right) \varphi
\]

(1.3)

Fig. 1.1 A test charge in a plasma attracts particles of opposite sign and repels particles of like sign, thus forming a shielding cloud that tends to cancel its charge.
If we define the electron and ion Debye lengths

\[ \lambda_{e,i} \equiv \left( \frac{T_{e,i}}{4\pi n_0 e^2} \right)^{1/2} \]  

(1.4)

and the total Debye length

\[ \lambda_D^{-2} = \lambda_e^{-2} + \lambda_i^{-2} \]  

(1.5)

Eq. (1.3) then becomes

\[ \frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{d\varphi}{dr} \right) = \lambda_D^{-2} \varphi \]  

(1.6)

Trying a solution of the form \( \varphi = \tilde{\varphi}/r \), we find

\[ \frac{d^2\tilde{\varphi}}{dr^2} = \lambda_D^{-2} \tilde{\varphi} \]  

(1.7)

The solution that falls off properly at large distances is \( \tilde{\varphi} \propto \exp(-r/\lambda_D) \). From elementary electricity and magnetism we know that the solution to (1.1) at locations very close to \( r = 0 \) is \( \varphi = q_T/r \); thus, the desired solution to (1.1) at all distances is

\[ \varphi = \frac{q_T}{r} \exp \left( \frac{-r}{\lambda_D} \right) \]  

(1.8)

The potential due to a test charge in a plasma falls off much faster than in vacuum. This phenomenon is known as Debye shielding, and is our first example of plasma collective behavior. For distances \( r \gg \) the Debye length \( \lambda_D \), the shielding cloud effectively cancels the test charge \( q_T \). Numerically, the Debye length of species \( s \) with temperature \( T_s \) is roughly \( \lambda_s \approx 740 [T_s(\text{eV})/n(\text{cm}^{-3})]^{1/2} \) in units of cm.

**EXERCISE** Prove that the net charge in the shielding cloud exactly cancels the test charge \( q_T \).

It is not necessary that \( q_T \) be a special particle. In fact, each particle in a plasma tries to gather its own shielding cloud. However, since the particles are moving, they are not completely successful. In an equal temperature plasma (\( T_e = T_i \)), a typical slowly moving ion has the full electron component of its shielding cloud and a part of the ion component, while a typical rapidly moving electron has a part of the electron component of its shielding cloud and almost none of the ion component.

### 1.3 Plasma Parameter

In a plasma where each species has density \( n_s \), the distance between a particle and its nearest neighbor is roughly \( n_s^{-1/3} \). The average potential energy \( \Phi \) of a particle due to its nearest neighbor is, in absolute value,

\[ |\Phi| \sim \frac{e^2}{r} \sim n_s^{1/3} e^2 \]  

(1.9)
Our definition of a plasma requires that this potential energy be much less than the
typical particle’s kinetic energy
\[
\frac{1}{2} m_s \langle v^2 \rangle = \frac{3}{2} \langle T_s \rangle = \frac{3}{2} m_s \nu_s^2
\]  
(1.10)
where \( m_s \) is the mass of species \( s \), \( \langle \ldots \rangle \) means an average over all particle velocities
at a given point in space, and we have defined the thermal speed \( \nu_s \) of species \( s \) by
\[
\nu_s \equiv \left( \frac{T_s}{m_s} \right)^{1/2}
\]  
(1.11)
For electrons, \( \nu_e \approx 4 \times 10^7 T_e^{1/2} \) (eV) in units of cm/s. Our definition of a
plasma requires
\[
n_0^{1/3} e^2 \ll T_e
\]  
(1.12)
or
\[
n_0^{2/3} \left( \frac{T_s}{n_0 e^2} \right) >> 1
\]  
(1.13)
Raising each side of (1.13) to the 3/2 power, and recalling the definition (1.4) of
the Debye length, we have (dropping factors of 4\( \pi \), etc.)
\[
\Lambda_s \equiv n_0 \lambda_D^3 >> 1
\]  
(1.14)
where \( \Lambda_s \) is called the plasma parameter of species \( s \). (Note: Some authors call \( \Lambda_s^{-1} \)
the plasma parameter.) The plasma parameter is just the number of particles of
species \( s \) in a box each side of which has length the Debye length (a Debye cube).
Equation (1.14) tells us that, by definition, a plasma is an ionized gas that has
many particles in a Debye cube. Numerically, \( \Lambda_s \approx 4 \times 10^8 T_s^{3/2} (eV)/n_0^{1/2} \text{cm}^{-3} \).
We will often substitute the total Debye length \( \lambda_D \) in (1.14), and define the result
\( \Lambda \equiv n_0 \lambda_D^3 \) to be the plasma parameter.

**EXERCISE** Evaluate the electron thermal speed, electron Debye length, and
electron plasma parameter for the following plasmas.
(a) A tokamak or mirror machine with \( T_e \approx 1 \text{ keV}, n_0 \approx 10^{13} \text{ cm}^{-3} \).
(b) The solar wind near the earth with \( T_e \approx 10 \text{ eV}, n_0 \approx 10^6 \text{ cm}^{-3} \).
(c) The ionosphere at 300 km above the earth’s surface with \( T_e \approx 0.1 \text{ eV}, n_0 \approx 10^6 \text{ cm}^{-3} \).
(d) A laser fusion, electron beam fusion, or ion beam fusion plasma with
\( T_e \approx 1 \text{ keV}, n_0 \approx 10^{20} \text{ cm}^{-3} \).
(e) The sun’s center with \( T_e \approx 1 \text{ keV}, n_0 \approx 10^{23} \text{ cm}^{-3} \).

It is fairly easy to see why many ionized gases found in nature are indeed plasmas. If the potential energy of a particle due to its nearest neighbor were greater than its
kinetic energy, then there would be a strong tendency for electrons and ions to
bind together into atoms, thus destroying the plasma. The need to keep ions and
electrons from forming bound states means that most plasmas have temperatures
in excess of one electron-volt.
**EXERCISE** The temperature of intergalactic plasma is currently unknown, but it could well be much lower than 1 eV. How could the plasma maintain itself at such a low temperature? *(Hint: $n_0 \approx 10^{-5}$ cm$^{-3}$).*

Of course, it is possible to find situations where a plasma exists jointly with another state. For example, in the lower ionosphere there are regions where 99% of the atoms are neutral and only 1% are ionized. In this *partially ionized plasma*, the ionized component can be a legitimate plasma according to (1.14), where $\Lambda_s$ should be calculated using only the parameters of the ionized component. Typically, there will be a continuous exchange of particles between the unionized gas and the ionized plasma, through the processes of atomic recombination and ionization.

We can now evaluate the validity of the assumption made before (1.3), that $e\omega / T_s \ll 1$. This assumption is most severe for the nearest neighbor to the test charge (which we now take to have charge $q_T = +e$). Using the unshielded form of the potential, we require

$$\frac{e}{T_s} \left( \frac{e}{r} \right) \approx \frac{e}{T_s} \left( \frac{e}{n_0^{-1/3}} \right) \ll 1$$

(1.15)

or

$$n_0^{1/3} e^2 \ll T_s$$

(1.16)

which is just the condition (1.12) required by the definition of a plasma. Thus, our derivation of Debye shielding is correct for any ionized gas that is indeed a plasma.

### 1.4 PLASMA FREQUENCY

Consider a hypothetical slab of plasma of thickness $L$, where for the present we consider the ions to have infinite mass, but equal density $n_0$, and opposite charge to the electrons while the electrons are held rigidly in place with respect to each other, but can move freely through the ions. Suppose the electron slab is displaced a distance $\delta$ to the right of the ion slab and then allowed to move freely (Fig. 1.2). What happens?

An electric field will be set up, causing the electron slab to be pulled back toward the ions. When the electrons exactly overlap the ions, the net force is zero, but the electron slab has substantial speed to the left. Thus, the electron slab overshoots, and the net result is harmonic oscillation. The frequency of the oscillation is called the *electron plasma frequency*. It depends only on the electron density, the electron charge, and the electron mass. Let’s calculate it.

Poisson’s equation in one dimension is ($\delta_x \equiv \partial / \partial x$)

$$\partial_x E = 4\pi \rho$$

(1.17)

where $E$ is the electric field. Referring to Fig. 1.3, we take the boundary condition $E(x = 0) = 0$, and assume throughout that $\delta \ll L$. From (1.17) the electric field over most of the slab is $4\pi n_0 e \delta$, and the force per unit area on the electron slab is (electric field) $\times$ (charge per unit area) or $-4\pi n_0 e^2 \delta L$. Newton’s second law is
Introduction

Fig. 1.2 Plasma slab model used to calculate the plasma frequency.

(force per unit area) = (mass per unit area) \times (acceleration), or

\[ (-4\pi n_0^2 e^2 \delta L) = (n_0 m_i L) (\ddot{\delta}) \]  \hspace{1cm} (1.18)

where an overdot is a time derivative. Equation (1.18) is in the standard form of a
harmonic oscillator equation,

\[ \ddot{\delta} + \left( \frac{4\pi n_0 e^2}{m_e} \right) \delta = 0 \]  \hspace{1cm} (1.19)

with characteristic frequency

\[ \omega_e \equiv \left( \frac{4\pi n_0 e^2}{m_e} \right)^{1/2} \]  \hspace{1cm} (1.20)

which is called the electron plasma frequency. Numerically, \( \omega_e = 2\pi \times 9000 n_e^{1/2} \)
(cm\(^{-1}\)) in units of s\(^{-1}\).

EXERCISE Calculate the electron plasma frequency \( \omega_e \) and \( \omega_e/2\pi \) (e.g., in MHz
and kHz) for the five plasmas in the exercise below (1.14).

By analogy with the electron plasma frequency (1.20) we define the ion plasma
frequency \( \omega_i \) for a general ion species with density \( n_i \) and ion charge \( Ze \) as

\[ \omega_i \equiv \left( \frac{4\pi n_i Z^2 e^2}{m_i} \right)^{1/2} \]  \hspace{1cm} (1.21)

The total plasma frequency \( \omega_p \) for a two-component plasma is defined as

\[ \omega_p^2 \equiv \omega_e^2 + \omega_i^2 \]  \hspace{1cm} (1.22)
(See Problem 1.3.) For most plasmas in nature $\omega_e \gg \omega_i$, so $\omega_p^2 \approx \omega_e^2$. We will see in a later chapter that the general response of an unmagnetized plasma to a perturbation in the electron density is a set of oscillations with frequencies very close to the electron plasma frequency $\omega_e$.

The relation among the Debye length $\lambda_s$, the plasma frequency $\omega_s$, and the thermal speed $v_s$, for the species $s$, is

$$\lambda_s = \frac{v_s}{\omega_s} \tag{1.23}$$

**EXERCISE** Demonstrate (1.23).

### 1.5 OTHER PARAMETERS

Many of the plasmas in nature and in the laboratory occur in the presence of magnetic fields. Thus, it is important to consider the motion of an individual charged particle in a magnetic field. The Lorentz force equation for a particle of charge $q_s$ and mass $m_s$ moving in a constant magnetic field $\mathbf{B} = B_0 \hat{z}$ is

$$m_s \ddot{\mathbf{r}} = \frac{q_s}{c} (\dot{\mathbf{r}} \times \mathbf{B}_0 \hat{z}) \tag{1.24}$$

For initial conditions $\mathbf{r}(t = 0) = (x_0, y_0, z_0)$ and $\mathbf{v}(t = 0) = (0, v_\perp, v_z)$ the solution of (1.24) is

$$x(t) = x_0 + \frac{v_\perp}{\Omega_s} (1 - \cos \Omega_s t)$$

$$y(t) = y_0 + \frac{v_\perp}{\Omega_s} \sin \Omega_s t$$

$$z(t) = z_0 + v_z t \tag{1.25}$$
where we have defined the gyrofrequency

\[
\Omega_s \equiv \frac{q_s B_0}{m_s c}
\]  

(1.26)

**EXERCISE** Verify that (1.25) is the solution of (1.24) with the desired initial conditions.

Numerically, \( \Omega_e = -2 \times 10^7 B_0 \) (gauss, abbreviated G) in units of \( s^{-1} \), and \( \Omega_i = 10^4 B_0 \) (gauss) in units of \( s^{-1} \) if the ions are protons.

The nature of the motion (1.25) is a constant velocity in the \( \hat{z} \)-direction, and a circular gyration in the \( x-y \) plane with angular frequency \(|\Omega_s|\) and center at the guiding center position \( r_{gc} \) given by

\[
r_{gc} = (x_0 + v_{x0}/\Omega_s, y_0, z_0 + v_{zf})
\]  

(1.27)

The radius of the circle in the \( x-y \) plane is the gyroradius \( v_{z0}/|\Omega_s| \). The mean gyroradius \( r_s \) of species \( s \) is defined by setting \( v_{z0} \) equal to the thermal speed, so

\[
r_s \equiv v_s/|\Omega_s|
\]  

(1.28)

**EXERCISE** In the exercise below (1.14), calculate and order the frequencies \( \omega_e, \omega_i, |\Omega_s|, \Omega_i \); also calculate the gyroradii \( r_e \) and \( r_i \); take \( T_i = T_e \) and use the following parameters.

(a) Protons, \( B_0 = 10 \) kG.
(b) Protons, \( B_0 = 10^{-5} \) G.
(c) \( O^+ \) ions, \( B_0 = 0.5 \) G.
(d) Deuterons, \( B_0 = 0 \) and \( B_0 = 10^6 \) G.
(e) Protons, \( B_0 = 100 \) G.

At this point, let us briefly mention relativistic and quantum effects. For simplicity, we shall always treat nonrelativistic plasmas. In principle, there is no difficulty in generalizing any of the results of this course to include special relativistic effects; these are discussed at length in the book by Clemmow and Dougherty [2].

**EXERCISE** To what regime of electron temperature are we limited by the nonrelativistic assumption? How about ion temperature if the ions are protons?

There are, of course, many plasmas in which special relativistic effects do become important. For example, cosmic rays may be thought of as a component of the interstellar and intergalactic plasma with relativistic temperature.

We shall also neglect quantum mechanical effects. For most of the laboratory and astrophysical plasmas in which we might be interested, this is a good assumption. There are, of course, plasmas in which quantum effects are very important. An example would be solid state plasmas. As a rough criterion for the neglect of quantum effects, one might require that the typical de Broglie length \( h/m_s v_s \) be much less than the average distance between particles \( n_0^{-1/3} \).
**EXERCISE** What is the maximum density allowed by this criterion for electrons with temperature
(a) 10 eV?
(b) 1 keV?
(c) 100 keV?

In other applications, such as collisions (see next section), one might require the de Broglie length to be much smaller than the distance of closest approach of the colliding particles.

In addition to these assumptions, we shall also neglect the magnetic field in many of the sections of this book. This neglect is made for simplicity, in order that the basic physical phenomena can be elucidated without the complications of a magnetic field. In practice, the magnetic field can usually be ignored when the typical frequency (inverse time scale) of a phenomenon is much larger than the gyrofrequencies of both plasma species.

### 1.6 COLLISIONS

A typical charged particle in a plasma is at any instant interacting electrostatically (see Problem 1.5) with many other charged particles. If we did not know about Debye shielding, we might think that a typical particle is simultaneously having Coulomb collisions with all of the other particles in the plasma. However, the field of our typical particle is greatly reduced from its vacuum field at distances greater than a Debye length, so that the particle is really not colliding with particles at large distances. Thus, we may roughly think of each particle as undergoing a simultaneous Coulomb collisions.

From our definition of a plasma, we know that the potential energy of interaction of each particle with its nearest neighbor is small. Since the potential energy is a measure of the effect of a collision, this means that the strongest one of its simultaneous collisions (the one with its nearest neighbor) is relatively weak. Thus, a typical charged particle in a plasma is simultaneously undergoing weak collisions. We shall soon see that even though \( A \) is a large number for a plasma, the total effect of all the simultaneous collisions is still weak. Of course, a weak effect can still be a very important effect. In the magnetic bottles like tokamaks and mirror machines currently being used to study controlled thermonuclear fusion plasmas, ion-ion collisions are one of the most important loss mechanisms.

Mathematically, the importance of collisions is contained in an expression called the *collision frequency*, which is the inverse of the time it takes for a particle to suffer a collision. Exactly what is meant by a collision of a charged particle depends upon the definition, and we will consider two different definitions with different physical content. Our mathematical derivation of the collision frequency is an approximate one, intended to be simple but yet to yield the correct results within factors of two or so. A more rigorous development can be found in the book by Spitzer [3]. (See Problem 1.6.)

Consider the situation shown in Fig. 1.4. A particle of charge \( q \), mass \( m \) is incident on another particle of charge \( q_0 \) and infinite mass with incident speed \( v_0 \).
If the incident particle were undeflected, it would have position \( x = v_0 t \) along the upper dashed line in Fig. 1.4, being at \( x = 0 \) directly above the scattering charge \( q_0 \) at \( t = 0 \). The separation \( p \) of the two dashed lines is the impact parameter. If the scattering angle is small, the final parallel speed (parallel to the dashed lines) will be quite close to \( v_0 \). The perpendicular speed \( v_\perp \) can be obtained by calculating the total perpendicular impulse

\[
m v_\perp = \int_{-\infty}^{\infty} dt \, F_\perp(t)
\]

where \( F_\perp \) is the perpendicular force that the particle experiences in its orbit. Since the scattering angle \( v_\perp/v_0 \) is small, we can to a good approximation use the unperturbed orbit \( x = v_0 t \) to evaluate the right side of (1.29). This approximation is a very useful one in plasma physics. In Fig. 1.4, Newton’s second law with the Coulomb force law is

\[
m \ddot{\vec{r}} = \frac{q q_0}{r^2} \hat{r}
\]

where \( \hat{r} \) is a unit vector in the \( r \)-direction. Then

\[
F_\perp = \frac{q q_0}{r^2} \sin \theta = \frac{q q_0 \sin \theta}{(p/\sin \theta)^2} = \frac{q q_0}{p^2} \sin^3 \theta
\]

where we have used \( p = r \sin \theta \) since the particle is assumed to be traveling along the upper dashed line. Equation (1.29) then reads

\[
v_\perp = \frac{q q_0}{m p^2} \int_{-\infty}^{\infty} dt \sin^3 \theta(t)
\]

The relation between \( \theta \) and \( t \) is obtained from

\[
x = -r \cos \theta = \frac{-p \cos \theta}{\sin \theta} = v_0 t
\]

so that

\[
dt = \frac{p}{v_0} \frac{d\theta}{\sin^2 \theta}
\]

**EXERCISE** Verify (1.34).

Using (1.34) in (1.32), we find

\[
v_\perp = \frac{q q_0}{m v_0 p} \int_0^\pi d\theta \sin \theta = \frac{2 q q_0}{m v_0 p}
\]

Defining the quantity
\[ p_0 \equiv \frac{2qq_0}{mv_0^2} \]  

we have

\[ \frac{v_{\perp}}{v_0} = \frac{p_0}{p} \]  

which is strictly valid only when \( v_{\perp} \ll v_0, p \gg p_0 \). In some books, the parameter \( p_0 \) is called the Landau length.

**EXERCISE** Show that if \( qq_0 > 0 \), then \( p_0 \) is the distance of closest possible approach for a particle of initial speed \( v_0 \).

Although (1.37) is not valid for large angle collisions, let us use it to get a rough idea of the impact parameter \( p \) which yields a large angle collision; we do this by setting \( v_{\perp} \) equal to \( v_0 \) in (1.37) to obtain \( p = p_0 \). Thus, any impact parameter \( p \leq p_0 \) will yield a large angle collision. Suppose the incident particle is an electron, and the (almost) stationary scatterer is an ion. (Although Fig. 1.4 shows a repulsive collision, our development is equally valid for attractive collisions.) The cross section for scattering through a large angle by one ion is \( \pi p_0^2 \). Consider an electron that enters a gas of ions. It will have a large angle collision after a time given roughly by setting (the total cross section of the ions in a tube of unit cross-sectional area, and length equal to the distance traveled) equal to (the unit area), or (time) \times (velocity) \times (number per unit volume) \times (cross section) = 1. The inverse of this time gives us the collision frequency \( \nu_L \) for large angle collisions; thus

\[ \nu_L = \pi n_0 v_0 p_0^3 = \frac{4\pi n_0 q^2 q_0^2}{m^2 v_0^3} = \frac{4\pi n_0 e^2}{m^2 v_0^3} \]  

Note that \( \nu_L \) is proportional to the inverse third power of the particle speed.

Recall that a typical charged particle in a plasma is simultaneously undergoing \( \Delta \) collisions. Only a very few of these are of the large angle type that lead to (1.38), since a large angle collision involves a potential energy of interaction comparable to the kinetic energy of the incident particle and, by the definition of a plasma, the potential energy of a particle due to its nearest neighbor is small compared to its kinetic energy. Thus, a particle undergoes many more small angle collisions than large angle collisions. It turns out that the cumulative effect of these small angle collisions is substantially larger than the effect of the large angle collisions, as we shall now show.

Unlike the large angle collisions, the many small angle collisions can produce a large effect only after many of them occur. But these small angle collisions produce velocity changes in random directions, some up, some down, some left, some right. We need to know how to measure the cumulative effect of many small random events.

Consider a variable \( \Delta x \) that is the sum of many small random variables \( \Delta x_i \), \( i = 1, 2, \ldots, N \),

\[ \Delta x = \Delta x_1 + \Delta x_2 + \ldots + \Delta x_N \]  

(1.39)
Suppose \( \langle \Delta x \rangle = 0 \) for each \( i \) and \( \langle (\Delta x)^{2} \rangle \) is the same for each \( i \), where \( \langle \cdot \rangle \) indicates ensemble average [4]. Furthermore, suppose \( \langle \Delta x_{i}, \Delta x_{j} \rangle = 0 \) if \( i \neq j \), so that \( \Delta x_{i} \) is uncorrelated with \( \Delta x_{j}, i \neq j \). Then by (1.39) we have \( \langle \Delta x \rangle = 0 \), and
\[
\langle (\Delta x)^{2} \rangle = \left( \sum_{i=1}^{N} \Delta x_{i} \right)^{2} = \sum_{i=1}^{N} \langle (\Delta x_{i})^{2} \rangle = N \langle \langle (\Delta x_{i})^{2} \rangle \rangle
\]  
(1.40)

Consider a typical particle moving in the z-direction through a gas of scattering centers. As it moves, it suffers many small angle collisions given by \( v_{\perp} \), which can be decomposed into random variables \( \Delta u_{x} \) and \( \Delta u_{y} \). These latter have just the properties of our random variable \( \Delta x_{i} \) above. For one collision, with a given impact parameter \( p \) (Fig. 1.5), we have from (1.37)
\[
\langle v_{\perp}^{2} \rangle = \langle (\Delta u_{y})^{2} \rangle + \langle (\Delta u_{x})^{2} \rangle = \frac{v_{0}^{2}p_{0}^{2}}{p^{2}}
\]  
(1.41)

Since \( \Delta u_{x} \) must have the same statistical properties as \( \Delta u_{y} \), we must have
\[
\langle (\Delta u_{x})^{2} \rangle = \langle (\Delta u_{y})^{2} \rangle = \frac{1}{2} \frac{v_{0}^{2}p_{0}^{2}}{p^{2}}
\]  
(1.42)

Then by (1.40) we have, for the total x velocity \( \Delta u_{x}^{\text{tot}} \),
\[
\langle (\Delta u_{x}^{\text{tot}})^{2} \rangle = \sum_{i=1}^{N} \langle (\Delta u_{x})^{2} \rangle = \frac{N}{2} \frac{v_{0}^{2}p_{0}^{2}}{p^{2}}
\]  
(1.43)

Since we are considering a particle moving through a gas of scattering centers, it is more useful for our purposes to have the time derivative of (1.43), where on the

![Fig. 1.5](image)

The incident particle is located at the origin and is traveling into the paper. It makes simultaneous small angle collisions with all of the scattering centers randomly distributed with impact parameters between \( p \) and \( p + dp \).
right we shall have \( dN/dt = 2\pi p \, dp \, n_0 v_0 \) as the number of scattering centers, with impact parameter between \( p \) and \( p + dp \), which our incident particle encounters per unit time. The time derivative of (1.43) is then

\[
\frac{d}{dt} \langle (\Delta v_{\perp}^{\text{tot}})^2 \rangle = \pi n_0 v_0^2 p_0^2 \frac{dp}{p} \tag{1.44}
\]

We have calculated (1.44) for only one set of impact parameters between \( p \) and \( p + dp \). The same logic that led to (1.40) also allows us to sum (integrate) the right side of (1.44) over all impact parameters to obtain a total change in mean square velocity in the \( \hat{x} \)-direction. Likewise, we can add the total \( \hat{x} \)-direction and the total \( \hat{y} \)-direction mean square velocities to obtain a total mean square perpendicular velocity \( \langle (\Delta v_{\perp}^{\text{tot}})^2 \rangle \). With this final factor of two we have

\[
\frac{d}{dt} \langle (\Delta v_{\perp}^{\text{tot}})^2 \rangle = 2\pi n_0 v_0^2 p_0^2 \int_{p_{\text{min}}}^{p_{\text{max}}} \frac{dp}{p} \tag{1.45}
\]

What should we use for \( p_{\text{max}} \) and \( p_{\text{min}} \)? Recall that our derivation of the scattering angle \( v_{\perp}/v_0 \) in (1.37) uses the Coulomb force law. However, we know from Section 1.2 that the true force law is modified by Debye shielding and is essentially negligible at distances (impact parameters) much greater than a Debye length. Thus, it is consistent with the approximate nature of the present calculation to replace \( p_{\text{max}} \) with \( \lambda_D \). In the case of \( p_{\text{min}} \), we use the fact that our scattering formula (1.37) is not valid for impact parameters \( p < |p_0| \) to replace \( p_{\text{min}} \) by \( |p_0| \). Equation (1.45) is then

\[
\frac{d}{dt} \langle (\Delta v_{\perp}^{\text{tot}})^2 \rangle = 2\pi n_0 v_0^2 p_0^2 \ln \left( \frac{\lambda_D}{|p_0|} \right) \tag{1.46}
\]

Since the logarithm is such a slowly varying function of its argument, it will suffice to make a very rough evaluation of \( \lambda_D/p_0 \). In the definition of \( p_0 \) in (1.36) we take \( q = -e, q_0 = +e, m = m_e \), and for this rough calculation replace \( v_0 \) by the electron thermal speed \( v_e \) to obtain

\[
\frac{\lambda_D}{|p_0|} \approx \frac{\lambda_D m_e v_e^2}{2e^2} = \frac{m_e \lambda_D^3 \omega_e^2}{2e^2} \approx 2\pi n_0 \lambda_D^3 = 2\pi \Lambda \tag{1.47}
\]

where we have ignored the difference between \( \lambda_D \) and \( \lambda_e \). Dropping the small factor \( 2\pi \) compared to the large plasma parameter \( \Lambda \), and using the definition (1.36) of \( p_0 \), we find that (1.46) becomes

\[
\frac{d}{dt} \langle (\Delta v_{\perp}^{\text{tot}})^2 \rangle = \frac{8\pi n_0 e^4}{m_e^2 v_0^3} \ln \Lambda \tag{1.48}
\]

A reasonable definition for the scattering time due to small angle collisions is the time it takes \( \langle (\Delta v_{\perp}^{\text{tot}})^2 \rangle \) to equal \( v_0^2 \) according to (1.48); the inverse of this time is the collision frequency \( \nu_e \) due to small-angle collisions:

\[
\nu_e = \frac{8\pi n_0 e^4 \ln \Lambda}{m_e^2 v_0^3} \tag{1.49}
\]

Note again the inverse cube dependence on the velocity \( v_0 \). One important aspect of \( \nu_e \) is that it is a factor 2 \( \ln \Lambda \) larger than the collision frequency \( \nu_L \) for large
angle collisions given by (1.38). This is a substantial factor in a plasma \( \Lambda = 14 \) if \( \Lambda = 10^6 \). Thus, the deflection of a charged particle in a plasma is predominantly due to the many random small angle collisions that it suffers, rather than the rare large angle collisions.

Throughout one's study of plasma physics, it is useful to identify each phenomenon as a collective effect or as a single particle effect. The oscillation of the plasma slab in Section 1.4, characterized by the plasma frequency \( \omega \), is a collective effect involving many particles acting simultaneously to produce a large electric field. The collisional deflection of a particle, represented by the collision frequency \( \nu \), in (1.49), is a single particle effect caused by many collisions with individual particles that do not act cooperatively.

**EXERCISE** Is the Debye shielding described in Section 1.2 a collective effect or a single particle effect?

It is instructive to calculate the ratio of \( \nu \) to \( \omega \), which is, taking a typical speed \( v_0 = v_e \) in (1.49),

\[
\frac{\nu}{\omega} \approx \frac{8\pi n_0 e^4}{m_e^2 v_e^3} \frac{\ln \Lambda}{\omega_e} = \frac{\ln \Lambda}{2\pi n_e \lambda_e^2} = \frac{\ln \Lambda}{2\pi \Lambda_e}
\]  
\[
(1.50)
\]

By crudely dropping the factor \( \ln \Lambda/2\pi \) and replacing \( \Lambda_e \) by \( \Lambda \), we have the easily remembered but very approximate expression

\[
\frac{\nu}{\omega} \approx \frac{1}{\Lambda}
\]  
\[
(1.51)
\]

Thus, the collision frequency in a plasma is very much smaller than the plasma frequency. In this respect, single particle effects are less important than collective effects. A wave with frequency near \( \omega \) will oscillate many times before being substantially damped because of collisions.

**EXERCISE** What is the ratio of the collisional mean free path, for a typical electron, to the electron Debye length?

The collision frequency \( \nu \) that we calculated in (1.49) is the one appropriate to the collisions of electrons with ions, \( \nu_{ei} \). The collision frequency \( \nu_{ee} \) of electrons with electrons could be calculated in the same way, by moving to the center-of-mass frame rather than taking the scattering center to have infinite mass. This procedure would only introduce factors of two or so, so that within such factors we have \( \nu_{ee} \approx \nu_{ei} \). Next, consider ion-ion collisions between ions having the same temperature as the electrons that have collision frequency \( \nu_{ei} \). Equation (1.49) yields, with \( m_e \) replaced by \( m_i \) and \( v_e = (m_e/m_i)^{1/2} v_i \), instead of \( v_0 \), \( v_0 = (m_e/m_i)^{1/2} \nu_{ee} \). Finally, consider ions scattered by electrons (or Mack trucks scattered by pedestrians). This calculation in the center-of-mass frame would introduce another factor of \( (m_e/m_i)^{1/2} \), so that \( v_{ii} \approx (m_e/m_i)^{1/2} \nu_{ee} \).

Suppose an electron-proton plasma is prepared in such a way that the electrons and protons have arbitrary velocity distributions, and comparable but not equal temperatures. On the time scale \( \nu_{ee}^{-1} \approx \nu_{ei}^{-1} \approx \Lambda \omega_e^{-1} \), the electrons will therma-
lize via electron-electron and electron-ion collisions and obtain a Maxwellian distribution. On a time scale 43 times longer, the ions will thermalize and obtain a Maxwellian at the ion temperature via ion-ion collisions. Finally, on a time scale 43 times longer still, the electrons and ions will come to the same temperature via ion-electron collisions.

This completes our brief introduction to the important basic concepts of plasma physics. In the next chapter, we shall consider the motion of single charged particles in electric and magnetic fields.

REFERENCES

PROBLEMS

1.1 Debye Shielding

In the discussion of Debye shielding in Section 1.2, suppose that the ions are infinitely massive and thus cannot respond to the introduction of the test charge. How does the answer change?

1.2 Potential Energy (Birdsall's Problem)

A sphere of plasma has equal uniform densities $n_0$ of electrons and infinitely massive ions. The electrons are moved to the surface of the sphere, which they cover uniformly. What is the potential energy in the system? Sketch the electric field and electric potential as a function of radius. If the electrons initially had temperature $T_e$, and it is found that the potential energy is equal to the total initial electron kinetic energy, what is the radius of the sphere in terms of the electron Debye length?

1.3 Total Plasma Frequency

In the discussion of the plasma frequency in Section 1.4, suppose the ions are not infinitely massive but have mass $m_i$. Modify the discussion to show that the slabs oscillate with the total plasma frequency defined in (1.22).

1.4 Plasma in a Gravitational Field

Consider an electron–proton plasma with equal temperatures $T = T_e = T_i$, no magnetic field, and a gravitational acceleration $g$ in the $-\hat{z}$-direction. We desire the
densities $n_e(z)$ and $n_i(z)$, where $z = 0$ can be thought of as the surface of a planet. If the electrons and ions were neutral, their densities would be given by the Boltzmann law $n_{e,i} \propto \exp\left(-\frac{m_{e,i}}{T} g z\right)$. Then the scale height $T/m_{e,i} g$ would be quite different for electrons and ions. However, this would give rise to huge electric fields that would tend to move ions up and electrons down. Taking into account the electric field, use the Boltzmann law and the initial guess that $n_e(z) \approx n_i(z)$, to be checked at the end of the calculation, to find self-consistent electron and ion density distributions.

1.5 Electrostatic Interaction

Show that in nonrelativistic plasma, the Coulomb force between two typical particles is much more important than the magnetic field part of the Lorentz force.

1.6 Collisions

Read Sections 5.1, 5.2, and 5.3 of Spitzer [3] and compare his treatment of collisions to our Section 1.6. Watch out for differences in notation, and explain all apparent differences of factors of two.
CHAPTER 2

Single Particle Motion

2.1 INTRODUCTION

A plasma consists of many charged particles moving in self-consistent electric and magnetic fields. The fields affect the particle orbits, and the particle orbits affect the fields. The general solution of any problem in plasma physics can be quite complicated. In this chapter, we consider the motion of a single charged particle moving in prescribed fields. After studying this part of the problem in isolation, we can proceed in following chapters to include these particle orbits in the self-consistent determination of the fields.

2.2 E x B DRIFTS

Consider a particle with $v_z = 0$ gyrating in a magnetic field $B_0$ in the $\hat{z}$-direction, with an electric field $E_0$ in the $-\hat{j}$-direction perpendicular to the magnetic field as in Fig. 2.1. (The symbol $\hat{a}$ always means a unit vector in the $a$-direction.) The electric field $E_0$ cannot accelerate the particle indefinitely, because the magnetic field will turn the particle. (The component of electric field $E_\parallel$, which we ignore here, can accelerate particles indefinitely. In a plasma, the resulting current usually acts to cancel the charge that caused the electric field in the first place. There are, however, important cases where this cancellation is hindered; for example, the earth's aurora, and tokamak runaway electrons.) What does happen? When the charge $q$, is positive, the ion is accelerated on the way down. This gives it a larger local gyroradius at the bottom of its orbit than at the top; recall that the gyroradius is $r_s = v_\parallel/\Omega_s$. Thus, the motion will be a spiral in the $x$-$y$ plane as shown in Fig. 2.2, where we have used the symmetry of the situation to draw the upward part of each orbit. We see that the orbit does not connect to itself, but has jumped a
certain distance to the left during one orbit. The net result is that the particle has a \textit{drift} velocity \( \mathbf{v}_d \) to the left. Let us guess how big the drift speed is. If we average over many gyroperiods, we see that the average acceleration is zero. Thus, the net force must be zero. The force downward is \( q_s \mathbf{E}_0 \), while the force upward is \( (q_s/c)\mathbf{v}_d \times \mathbf{B}_0 \). We must have

\[
\overline{m_s \dot{\mathbf{v}}} = 0 = q_s \mathbf{E}_0 + \frac{q_s}{c} \mathbf{v}_d \times \mathbf{B}_0 \tag{2.1}
\]

where \( \overline{\ldots} \) indicates an average over one gyroperiod. Taking the cross product of (2.1) with \( \mathbf{B}_0 \), and assuming \( \mathbf{v}_d \cdot \mathbf{B}_0 = 0 \), we find

\[
\mathbf{v}_d = c \frac{\mathbf{E}_0 \times \mathbf{B}_0}{\mathbf{B}_0^2} \tag{2.2}
\]

Note that the drift velocity does not depend on the particle’s charge or mass.

**ExerciSe** What is the drift speed of an electron in the earth’s magnetosphere if \( |\mathbf{B}_0| = 0.1 \text{ G} \) and \( |\mathbf{E}_0| = 10^{-3} \text{ V cm}^{-1} \)? (Remember 1 sV = 300 V.) What if the particle were a uranium atom with charge \( q_s = +57 \ e \)?

Let us now make sure that our guess is correct, and that the kind of motion we have in mind, namely a gyration about the magnetic field lines, accompanied by a drift, is an exact solution to the equation of motion. This equation is

\[
m_s \ddot{\mathbf{v}} = q_s \mathbf{E}_0 + \frac{q_s}{c} \mathbf{v} \times \mathbf{B}_0 \tag{2.3}
\]
We define a new variable $\tilde{v}$ by splitting $v$ into a piece $\tilde{v}$ (which will turn out oscillatory) and a piece $v_d$ as given by (2.2). Taking

$$v = \tilde{v} + v_d$$

(2.4)

(2.3) becomes

$$m\ddot{\tilde{v}} = q_e E_0 + \frac{q_s}{c} \tilde{v} \times B_0 + \frac{q_s}{c} v_d \times B_0$$

$$= q_e E_0 + \frac{q_s}{c} \tilde{v} \times B_0 + \frac{q_s}{B_0^2} (E_0 \times B_0) \times B_0$$

$$= \frac{q_s}{c} \tilde{v} \times B_0$$

(2.5)

But the final form of (2.5) is an equation that we have already solved in (1.25) with a solution that represents gyromotion about the magnetic field. Adapting that solution we find

$$\tilde{v} = v_\perp (\sin \Omega_s t, \cos \Omega_s t, 0)$$

(2.6)

where $v_\perp$ is any constant. Thus, the total solution is

$$v = v_\perp (\sin \Omega_s t, \cos \Omega_s t, 0) + c \frac{E_0 \times B_n}{B_0^2}$$

(2.7)

Note that any constant $v_\perp$ is acceptable, including $v_\perp = 0$.

**EXERCISE** What is the initial velocity implied by the solution (2.7) with $v_\perp = 0$? Sketch orbits with $v_\perp = 0$, $v_\perp < v_d$, $v_\perp = v_d$, and $v_\perp > v_d$.

Note that this entire discussion would apply if an arbitrary (temporally and spatially constant) force $F_\perp$ such that $F_\perp \cdot B_0 = 0$ were to replace $q_e E_0$ in the force equation (2.1). Thus, instead of the drift velocity (2.2), we obtain

$$v_d = \frac{c}{q_s} \frac{F_\perp \times B_0}{B_0^2} = \frac{1}{\Omega_s} \left( \frac{F_\perp}{m_s} \times \hat{B}_0 \right)$$

(2.8)

**EXERCISE** What is the gravitational drift speed of an electron in a tokamak, with $|B_0| = 10$ kG? How about a proton? Does either of these drifts make it hard to confine a plasma in a volume of order $(1 \text{ m})^3$ for a time of order 1 s?

We proceed to discuss other kinds of drifts. We have already seen that any real force gives a drift according to (2.8). We shall now see that any so-called “fictitious” force also gives a drift. For example, it is sometimes said that magnetic fields exert a “pressure.” This is, of course, not a real pressure, yet we shall find that corresponding to magnetic “pressure” is a drift related to $\nabla B_0$. Likewise, when an existing drift speed changes, the resulting acceleration is experienced as an “inertial” force, which then gives rise to its own drift.
2.3 GRAD-B DRIFT

First, let us calculate the so-called grad-B drift. To do this we need to have a feeling for expansion techniques. Suppose we have an equation for a variable $x$, with one small term of size $\epsilon$, expressed as

$$f(x) - \epsilon g(x) = 0 \quad (2.9)$$

Here, $\epsilon$ is a small constant, $f$ and $g$ can represent a general integro-differential operator, and the solution of (2.9) when $\epsilon = 0$ is $x_0$, so that $f(x_0) = 0$. We can look for a solution $x$ to (2.9) of the form

$$x = x_0 + \epsilon x_1 + \epsilon^2 x_2 + \ldots \quad (2.10)$$

Inserting (2.10) in (2.9) yields

$$f(x_0 + \epsilon x_1 + \epsilon^2 x_2 + \ldots) = \epsilon g(x_0 + \epsilon x_1 + \epsilon^2 x_2 + \ldots) \quad (2.11)$$

After Taylor expanding $f$ and $g$, one obtains

$$f(x_0) + \frac{df}{dx_0} (\epsilon x_1 + \epsilon^2 x_2 + \ldots) + \frac{1}{2} \frac{d^2f}{dx_0^2} (\epsilon x_1 + \epsilon^2 x_2 + \ldots)^2$$

$$+ \ldots = \epsilon \left[ g(x_0) + \frac{dg}{dx_0} (\epsilon x_1 + \epsilon^2 x_2 + \ldots) + \ldots \right] \quad (2.12)$$

where $df/dx_0 \equiv df/dx|_{x_0}$, etc. Equating the coefficients of each power of $\epsilon$ yields

$$f(x_0) = 0 \quad (2.13)$$

which determines $x_0$, and

$$x_1 \frac{df}{dx_0} = g(x_0) \quad (2.14)$$

which determines

$$x_1 = \frac{g(x_0)}{df/dx_0}.$$

The approximate solution $x = x_0 + \epsilon x_1$ is called the "solution of (2.9) to order $\epsilon$." (Caution: some authors call this "the solution to order $\epsilon^2$.") We must always be careful with what we mean by small in these discussions. Something is "of order $\epsilon$" if it goes to zero as $\epsilon \to 0$; thus, $10^{-133} \epsilon$ is of order $\epsilon$ while $10^{-133}$ is of order one.

Consider a particle gyrating in a magnetic field $B_0\hat{z}$ that increases in the $\hat{y}$-direction, as shown in Fig. 2.3. Let us guess what happens. The gyroradius will be smaller at large $y$ than at small $y$, so the particle will drift as shown in Fig. 2.4 for

![Diagram](image-url)
ions and in Fig. 2.5 for electrons. Thus, electrons and ions drift in opposite directions and, in a plasma, a net current results.

The force on a charged particle is

$$ m_s \dot{v} = \frac{q_s}{c} (v \times B) \tag{2.15} $$

Taylor expanding $B$ about the guiding center of the particle,

$$ B = B_0 + (r \cdot \nabla)B_0 \tag{2.16} $$

where $B_0$ is measured at the guiding center, and where $r$ is measured from the guiding center (see Section 1.5), and inserting in (2.15), one obtains

$$ m_s \dot{v} = \frac{q_s}{c} (v \times B_0) + \frac{q_s}{c} [v \times (r \cdot \nabla)B_0] \tag{2.17} $$

**EXERCISE** What assumption is being made in (2.16)?

Expanding

$$ v = v_0 + v_1 \tag{2.18} $$

we have

$$ m_s \dot{v}_0 = \frac{q_s}{c} (v_0 \times B_0) \tag{2.19} $$

which yields gyromotion, and

$$ m_s \dot{v}_1 = \frac{q_s}{c} (v_1 \times B_0) + \frac{q_s}{c} [v_0 \times (r \cdot \nabla)B_0] \tag{2.20} $$

where we are treating $r \cdot \nabla$ as a small quantity, and to be consistent $r$ must be calculated using only $v_0$. 

---

**Fig. 2.4** Ion $\nabla B$ drift.

**Fig. 2.5** Electron $\nabla B$ drift.
Now we are only interested in that part of \( \mathbf{v}_1 \) that represents steady drift motion; therefore, after averaging both sides of (2.20) over a gyroperiod, upon which the left side vanishes, we have

\[
0 = \frac{q_s}{c} \mathbf{v}_1 \times \mathbf{B}_0 + \frac{q_s}{c} \mathbf{[v}_0 \times (\mathbf{r} \cdot \nabla)\mathbf{B}_0]}
\]

(2.21)

Taking \( \mathbf{v}_1 \perp \mathbf{B}_0 \), we obtain

\[
\mathbf{v}_1 = \frac{1}{B_0^2} \mathbf{[v}_0 \times (\mathbf{r} \cdot \nabla)\mathbf{B}_0] \times \mathbf{B}_0}
\]

(2.22)

Since the magnetic field \( \mathbf{B} \) varies only in the \( \hat{z} \)-direction,

\[
(\mathbf{r} \cdot \nabla)\mathbf{B}_0 = y \frac{\partial B_0}{\partial y} \hat{z}
\]

(2.23)

Then

\[
\mathbf{v}_0 \times (\mathbf{r} \cdot \nabla)\mathbf{B}_0 = \begin{vmatrix}
\hat{i} & \hat{j} & \hat{k} \\
v_{0x} & v_{0y} & 0 \\
0 & 0 & \frac{\partial B_0}{\partial y}
\end{vmatrix} = \hat{i}v_{0y}y \frac{\partial B_0}{\partial y} - \hat{j}v_{0x}y \frac{\partial B_0}{\partial y}
\]

(2.24)

From (1.25) and (1.27),

\[
\mathbf{r} = \left( \frac{-v_0}{\Omega_s} \cos \Omega_s t, \frac{v_0}{\Omega_s} \sin \Omega_s t, 0 \right)
\]

(2.25)

while (2.6) can be written

\[
v_0 = v_0(\sin \Omega_s t, \cos \Omega_s t, 0)
\]

(2.26)

When we average the right side of (2.24) over a gyroperiod, the first term vanishes, and the second term yields for (2.22), using \( \sin^2 \Omega_s t = 1/2 \),

\[
v_1 = -\frac{1}{2B_0^2} \frac{\partial B_0}{\partial y} \hat{x}
\]

(2.27)

or

\[
v_1 = \frac{1}{2B_0^2} \frac{v_{0z}^2}{\Omega_s} (\mathbf{B}_0 \times \nabla \mathbf{B}_0)
\]

(2.28)

This is the grad-\( B \) drift. Recalling that \( \Omega_s \) contains the sign of the charge, we see that the drift is in opposite directions for electrons and ions.

**EXERCISE** Given an electron and a proton with equal energies, compare the magnitude of the grad-\( B \) drifts.

### 2.4 CURVATURE DRIFTS

Suppose a particle is moving along a field line while gyrating about it. If the field line curves, without changing magnitude, then the particle tries to follow the field line because all motions across field lines are resisted. It therefore feels a centrifugal
force $\mathbf{F}_c$ outward (Fig. 2.6), equal to

$$\mathbf{F}_c = \frac{mv^2}{R_B} \hat{R}_B$$

(2.29)

Our general drift equation (2.8) then predicts

$$v_d = \frac{c}{q_s} \frac{\mathbf{F}_\perp \times \mathbf{B}_0}{B_0^2} = \frac{cmv^2}{R_B q_s B_0^2} \hat{R}_B \times \mathbf{B}_0$$

(2.30)

or

$$v_d = \frac{v^2}{\Omega B} (\hat{R}_B \times \mathbf{B}_0)$$

(2.31)

This is the curvature drift.

In a cylindrically symmetric vacuum field, it turns out that $\nabla B_0 = (-B_0/R_B)\hat{R}_B$ (see p. 26 of Ref. [1]); thus we may add the grad-B drift to the curvature drift to obtain

$$v_{d,\text{tot}} = \frac{(\hat{R}_B \times \hat{B}_0)}{\Omega B} \left( \frac{v^2}{2} + \frac{1}{2} v_0^2 \right)$$

(2.32)

where we recall that $v_0$ is the perpendicular speed. A rigorous derivation of (2.31) and (2.32) can be found in Refs. [2] and [3].

Fig. 2.6 Centrifugal force felt by a particle moving along a curved field line.
2.5 POLARIZATION DRIFT

We discuss next a drift that is the result of an electric field which varies with time. Since the drift is opposite for oppositely charged particles, it leads to a current called the polarization current. Consider a constant magnetic field $B_0 \hat{z}$, and an electric field $E(t) = -\dot{E} \hat{y}$, where $\dot{E}$ is a constant (Fig. 2.7). The force equation is

$$m \ddot{v} = q_s \dot{E} \hat{y} + \frac{q_e}{c} v \times B_0$$  \hspace{1cm} (2.33)

We expect an $E \times B_0$ drift in the $(-)\hat{x}$-direction, which will be increasing with time. Thus, the particle is being accelerated in the $(-)\hat{x}$-direction and, therefore, feels an effective force in the $\hat{z}$-direction. (The effective force is in the direction opposite to the acceleration; when one steps on the gas pedal of a car, one is forced backward into the seat.) This effective force should give rise to an $F \times B$ drift in the $\hat{y}$-direction. Using this intuition, we consider a solution of (2.33) of the form

$$v = v_0 + v_E \hat{x} + v_p \hat{y}$$  \hspace{1cm} (2.34)

where $v_0$ will contain all gyromotion, $v_E$ is the $E \times B$ drift, and $v_p$ is the polarization drift, which is assumed to be constant. Substituting (2.34) into (2.33), we obtain

$$m(\ddot{v}_0 + \ddot{v}_E) = -q_s \dot{E} \hat{y} + \frac{q_e}{c} v_0 \times B_0 - \frac{q_s}{c} v_E B_0 \hat{y} + \frac{q_e}{c} v_p B_0 \hat{z}$$  \hspace{1cm} (2.35)

The assumed nature of the solution indicates the separation of this equation into pieces, with

$$m \ddot{v}_0 = \frac{q_e}{c} v_0 \times B_0$$  \hspace{1cm} (2.36)

representing gyromotion,

$$m \ddot{v}_E = \frac{q_e}{c} v_p B_0 \hat{x}$$  \hspace{1cm} (2.37)

giving the polarization drift, and

$$0 = -q_s \dot{E} \hat{y} - \frac{q_e}{c} v_E B_0 \hat{y}$$  \hspace{1cm} (2.38)

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fig27.png}
\caption{Configuration that leads to a polarization drift.}
\end{figure}
giving the \( \mathbf{E} \times \mathbf{B} \) drift, namely,

\[
v_{E}\hat{x} = -\frac{c\dot{E}t}{B_0} \hat{x} = c \frac{\mathbf{E} \times \mathbf{B}_0}{B_0^2}
\]

(2.39)

Then (2.37) yields the polarization drift

\[
v_p = \frac{cm_s}{q_i B_0} (-) \frac{c\dot{E}}{B_0} = -\frac{c}{\Omega_s} \frac{\dot{E}}{B_0}
\]

(2.40)

which in vector form is

\[
v_p = \frac{c}{\Omega_s B_0} \frac{d}{dt} \mathbf{E}
\]

(2.41)

We see that (2.34) is an exact solution to (2.33).

**EXERCISE** If \( E(t) = E_0 \cos \omega t \), can you invent a criterion for the validity of (2.41) at each instant of time?

The polarization drift leads to a polarization current \( J_p \), of electrons and protons, given by

\[
J_p = n_e (v_{pe} - v_{pe}) = \frac{n_0 c^2}{B_0^2} \frac{dE}{dt} (m_e + m_i)
\]

(2.42)

or

\[
J_p = \frac{\rho_m c^3}{B_0^2} \frac{dE}{dt}
\]

(2.43)

where \( \rho_m \) is the mass density.

### 2.6 MAGNETIC MOMENT

The preceding sections have discussed drifts due to “forces” perpendicular to the magnetic field. There are also forces parallel to the magnetic field that are very important, leading to the concepts of **magnetic moment** and **adiabatic invariants**.

Recall that the **magnetic moment** of a current loop with current \( I \), area \( A \), in c.g.s. units, is

\[
\mu = \frac{IA}{c}
\]

(2.44)

A charged particle gyrating in a magnetic field is such a current loop, with current \( q_s \Omega_s / 2\pi \), area \( \pi \rho_s^2 = \pi v_{\perp}^2 / \Omega_s^2 \) (\( \rho_s \) is the gyroradius), and magnetic moment

\[
\mu = \frac{q_s \Omega_s}{2\pi c} \frac{v_{\perp}^2}{\Omega_s^2} = \frac{q_s v_{\perp}^2}{2c \Omega_s} = \frac{\sqrt{2} m_s v_{\perp}^2}{B}
\]

(2.45)

or

\[
\mu = \frac{W_{\perp}}{B}
\]

(2.46)
where $W_{\perp} = \frac{1}{2} m_{s} v_{\perp}^2$ is that portion of a particle’s kinetic energy which is perpendicular to the magnetic field.

We know that magnetic moments feel a force $-\mu \nabla B$ in an inhomogeneous magnetic field. How does this work out for a charged particle? Consider a particle gyrating about the axis of a cylindrically symmetric magnetic field, whose magnitude is changing along the axis, as shown in Fig. 2.8.

**EXERCISE** Does the field in Fig. 2.8 satisfy Maxwell’s equations?

In the figure, the vertical line is a side view of the gyrating particle. Notice that at the top of the orbit (Fig. 2.9), for a positively charged particle, the $\mathbf{v} \times \mathbf{B}$ force has one component giving gyromotion about the field, and another component pointing in the $(-)\hat{x}$-direction. This latter component is constant around the gyro-orbit, and the particle is steadily accelerated away from regions of strong field.

**EXERCISE** Show that this works the same for either sign of the charge.

The force in the $(-)\hat{x}$-direction, evaluated anywhere on the orbit, is

$$F = \frac{q_{z}}{c} (\mathbf{v} \times \mathbf{B})_{x} = \frac{|q_{z}|}{c} v_{\perp} B_{r}, \quad (2.47)$$

where $r$ is the distance from the $x$-axis, and $B_{r}$ is the component of the magnetic field in the $y$-$z$ plane in Fig. 2.8. In cylindrical coordinates,

$$\nabla \cdot \mathbf{B} = 0 = \frac{\partial B_{x}}{\partial x} + \frac{1}{r} \frac{\partial}{\partial r} (r B_{r})$$

Solving this equation with $B_{r} = 0$ at $r = 0$, and $B_{r} << B_{x}$ everywhere, one ob-
\[ B_r = - \frac{r}{2} \frac{\partial B_x}{\partial x} = - \frac{r}{2} |\nabla B| \quad (2.48) \]

Inserting (2.48) in (2.47), with \( r \) equal to the gyroradius \( \rho_s \), we obtain
\[ F = - \frac{|q_s|}{c} \frac{\rho_s}{2} v_\perp \nabla B = - \frac{m_s v_\perp^2}{2B} \nabla B \quad (2.49) \]
or
\[ F = -\mu \nabla B \quad (2.50) \]
as expected.

Knowing the force on the particle allows the calculation of its orbit. First one needs to know how the magnetic moment \( \mu \) changes along the orbit. The remarkable fact is that the magnetic moment is constant along the orbit, provided the field does not change much in one gyroperiod. Let us prove this.

The Lorentz force on a charged particle (with \( E = 0 \)) is \( F = (q_s/c)v \times B \). A small component \( F_\perp \) of this force acts to accelerate the particle in the direction perpendicular to the local magnetic field and parallel to the component of the particle velocity \( v_\perp \) used in the definition of \( \mu \). (In Fig. 2.8, let the particle shown have a positive velocity component \( v_\parallel \) along \( \hat{x} \). Then at the top of the orbit, \( v \times B \) has a component of magnitude \(|v_\parallel B_\perp|\) pointing into the paper.) This force is into the paper at the top of the orbit of the particle in Fig. 2.8, and is given by
\[ F_\perp = -\frac{q_s}{c} v_\parallel B_r \quad (2.51) \]
where \( v_\parallel \) is the component of velocity in the \( \hat{x} \)-direction and \( B_r \) is negative. The perpendicular energy of the particle then changes with time according to
\[ \frac{d}{dt} \left( \frac{1}{2} m_s v_\perp^2 \right) = v_\perp F_\perp = -\frac{q_s}{c} v_\perp v_\parallel B_r \quad (2.52) \]
When we use (2.48), this becomes (with \( r = \rho_s \) at the location of the particle)
\[ \frac{d}{dt} W_\perp = \frac{q_s}{c} v_\perp v_\parallel \frac{\rho_s}{2} \frac{\partial B_x}{\partial x} = \frac{1}{2} m_s v_\perp^2 v_\parallel \frac{1}{B} \frac{\partial B}{\partial x} \quad (2.53) \]
where \( B_x = B_r \), or
\[ \frac{d}{dt} W_\perp = W_\perp v_\parallel \frac{1}{B} \frac{\partial B}{\partial x} \quad (2.54) \]

**Exercise** Combine (2.50) and (2.53) to show that total energy is conserved.

The time rate of change of the magnetic moment is
\[ \frac{d\mu}{dt} = \frac{d}{dt} \left( \frac{W_\perp - W_\parallel}{B} \right) = \frac{1}{B} \frac{dW_\perp}{dt} - \frac{1}{B^2} W_\perp \frac{dB}{dt} \]
\[ = W_\perp v_\parallel \frac{1}{B^2} \frac{\partial B}{\partial x} - \frac{1}{B^2} W_\perp v_\parallel \frac{\partial B}{\partial x} \]
\[ = 0 \quad (2.55) \]
where the rate of change of $B$ along the particle orbit $\frac{dB}{dt} = v_\parallel \frac{\partial B}{\partial x}$ has been used. Thus,

$$\mu = \text{constant}$$

(2.56)

along the particle orbit, to within the accuracy of this calculation. This is an example of an adiabatic invariant, a quantity that is constant under slow changes in an external parameter. Although our derivation treated spatially varying magnetic fields, the same result holds for magnetic fields with slow time variation.

We are now in the position to understand the principle of mirror confinement, which is the basis for one of the two major approaches to magnetic fusion, and is also the reason for the existence of the earth’s magnetosphere. Consider a magnetic field created by two coils, as shown in Fig. 2.10. A particle that starts at $x = 0$ with energy $W_0$ and magnetic moment $\mu$ conserves both of these quantities. Suppose the particle initially has $v_\parallel > 0$; it moves to the right and feels a force to the left, $F = -\mu \nabla B$. Does the particle get reflected by the force, or does it go past $x = x_0$ to be lost from the machine? This will depend on its initial $v_\parallel^0$ and $v_\perp^0$. We have

$$\mu = \frac{\frac{1}{2} m v_\perp^2}{B} = \frac{\frac{1}{2} m v_\perp^0}{B_{\min}} = \text{const}$$

(2.57)

and

$$W = \frac{1}{2} m (v_\perp^2 + v_\parallel^2) = W_0 = \text{const}$$

(2.58)

As the particle moves to the right, $B$ increases and $W_\perp = \frac{1}{2} m v_\perp^2$ must increase to satisfy (2.57). If $W_\perp$ ever reaches $W_0$, then all the energy will be in perpendicular motion, $v_\parallel$ will vanish, and the particle will be reflected back toward the mirror machine. This happens if

$$\mu = \frac{\frac{1}{2} m v_\perp^0}{B_{\min}} > \frac{W_0}{B_{\max}} = \frac{\frac{1}{2} m (v_\perp^0 + v_\parallel^0)}{B_{\max}}$$

(2.59)

or

$$\frac{v_\perp^0}{v_\parallel^0 + v_\perp^0} > \frac{B_{\min}}{B_{\max}}$$

(2.60)

Defining the pitch angle $\theta = \tan^{-1}(v_\perp^0/v_\parallel^0)$, we have from (2.60)

Fig. 2.10 Simple mirror machine configuration.
\[
\sin \theta > \left( \frac{B_{\text{min}}}{B_{\text{max}}} \right)^{1/2} = \frac{1}{R^{1/2}}
\]  
(2.61)

where we have introduced the mirror ratio \( R \equiv B_{\text{max}}/B_{\text{min}} \). Particles whose pitch angles satisfy (2.61) at the center of the machine are confined. Those that do not are lost out from the ends. While our derivation applies only to particles circling the central magnetic field line, a similar statement is true for off-axis particles.

### 2.7 Adiabatic Invariants

The magnetic moment, constant under slow spatial or temporal changes in the magnetic field, is one example of an adiabatic invariant. It often turns out that in a system with a coordinate \( q \), and its conjugate momentum \( p \), the action, defined by

\[
J = \oint p \, dq
\]

is a constant under a slow change in an external parameter. Here, we have assumed that when there is no change in the external parameter, the motion is periodic, and \( \oint \) represents an integral over one period of the motion. In the case of a charged particle in a magnetic field, we could take, for example, measuring \( x \) from the guiding center: \( p = m v_x, \ q = x \), and

\[
J = \oint m_x v_x \, dx = \oint 2\pi/\Omega_x \, m_x v_x^2 \sin^2 (\Omega t) \, dt
\]

\[
= \frac{\pi m_x v_x^3}{\Omega_x} = \frac{2m_x \pi c}{q_x} \left( \frac{W_0}{B} \right) = \frac{2m_x \pi c}{q_x} \mu
\]

(2.63)

which is the magnetic moment to within a constant.

One famous example of the constancy of action was derived at the 1911 Solvay conference, where Lorentz asked: “What happens if we slowly shorten the string of a swinging pendulum?” The next morning, Einstein answered: “Action [= energy/frequency] is conserved.”

Let us now demonstrate the invariance of the action in the general case. We have in mind the picture of a particle bouncing in a potential well, with the shape of the well changing slowly with time, as shown in Fig. 2.11. In Hamiltonian mechanics, we have a Hamiltonian \( H(p, q, \lambda) \) where \( p \) is the momentum (\( mx \) in the

![Fig. 2.11](image_url) Periodic motion in a slowly changing potential well.
Single Particle Motion

$q$ is the coordinate ($x$ in the figure), and $\lambda$ is the parameter that determines the shape of the well. When $\lambda$ is constant, the Hamiltonian is constant; when $\lambda$ changes,

$$\frac{dH}{dt} = \frac{\partial H}{\partial \lambda} \frac{d\lambda}{dt}$$  \hspace{1cm} (2.64)

The Hamiltonian equations of motion are

$$\dot{q} = \frac{\partial H}{\partial p}, \quad \dot{p} = -\frac{\partial H}{\partial q}$$  \hspace{1cm} (2.65)

The time derivative of the action

$$J = \oint p \, dq = 2 \int_{q_1}^{q_2} p \, dq$$  \hspace{1cm} (2.66)

is

$$J = 2 \int_{q_1}^{q_2} \dot{p} \, dq + 2p(q_2) \dot{q}_2 - 2p(q_1) \dot{q}_1$$  \hspace{1cm} (2.67)

The last two terms vanish since the momentum is zero at the turning points; then

$$J = -2 \int_{q_1}^{q_2} \frac{\partial H}{\partial q} \, dq = -2[H(q_2) - H(q_1)] = 0$$  \hspace{1cm} (2.68)

since $\partial H/\partial q$ is to be taken at fixed $\lambda$, implying $H(q_2)$ and $H(q_1)$ are to be taken at fixed $\lambda$, and $H$ is a constant except for its variation with $\lambda$. We have thus shown the approximate constancy of any action variable in the presence of periodic motion and slow changes of external parameters. Note that the present derivation is heuristic, since it has been assumed that the variation is so slow that the turning points $q_2(t)$ and $q_1(t)$ can be treated as continuous functions of time and can be differentiated as in (2.67) [4]. A rigorous treatment of this problem can be found in the fundamental paper of Kruskal [5]; see also Goldstein [6].

The knowledge of an adiabatic invariant can be very useful in predicting particle behavior. Let us return to the mirror machine, where the constancy of the magnetic moment adiabatic invariant has already enabled us to determine which particles will be confined and which will be lost. Consider a confined particle. The confined particle executes periodic motion between $x_1$ and $x_2$. Thus,

$$J_2 = \oint p \, dq = \oint mv_x \, dx$$  \hspace{1cm} (2.69)

must be a constant of the motion, even when the entire mirror field undergoes slow temporal changes, or when the mirror field is not axisymmetric.

There is yet a third adiabatic invariant. As the charged particle bounces from $x_1$ to $x_2$, it drifts perpendicular to the field lines, with speed $v_d$. Eventually, it comes all the way around the mirror machine. Because this is like a huge gyro-orbit about the axis of the magnetic field, we define a new adiabatic invariant

$$J_3 = \oint v_d \, dl$$  \hspace{1cm} (2.70)

where $l$ is the distance around the mirror machine measured at some fixed $x$, for example $x_1$. It turns out that $J_3$ is proportional to the total magnetic flux enclosed by the drifting motion. This invariant is useful when the mirror field is not axisymmetric, or when it undergoes slow temporal changes.
EXERCISE Sketch the earth’s magnetosphere, and discuss the motion leading to $\mu$, $J_2$, and $J_3$.

2.8 PONDEROMOTIVE FORCE

All of the examples of single particle motion considered in previous sections involve motion in a magnetic field, with or without an electric field. There is one very important single particle effect, the ponderomotive force or Miller force, that occurs in spatially varying high frequency electric fields, with or without an accompanying magnetic field. Consider a charged particle oscillating in a high frequency electric field $E(t) = E_0 \cos(\omega t)$. The motion is then a sinusoidal variation of distance with time, as shown in Fig. 2.12. Now suppose the electric field has an amplitude that varies smoothly in space, $E(x,t) = E_0(x) \cos(\omega t)$, being stronger to the right and weaker to the left. Then the first oscillation brings the particle into regions of strong field, where it can be given a strong push to the left (see Fig. 2.13). When the field turns around, the particle is in a region of weaker field, and the push to the right is not as strong. The net result is a displacement to the left, which continues in succeeding cycles as an acceleration away from the region of strong field [7].

Mathematically, the force equation is

$$m_0 \ddot{x} = q_0 E = q_0 E_0(x) \cos \omega t$$

(2.71)

It is convenient to decompose $x$ into a slowly varying component $x_0$, called the oscillation center (compare this concept to the guiding center in a magnetic field) and a rapidly varying component $x_1$, $x = x_0 + x_1$. Here, $x_0 = \bar{x}$ where $\bar{\cdot}$ indicates a time average over the short time $2\pi/\omega$. Making a Taylor expansion of

---

Fig. 2.12 Sinusoidal motion of a charged particle in a high-frequency electric field.
Fig. 2.13 Motion of a charged particle in a high-frequency electric field that is weaker to the left and stronger to the right.

$E_0(x)$ about the oscillation center $x_0$, (2.71) becomes

$$m_s(x_0 + \ddot{x}_1) = q_s \left( E_0 + x_1 \frac{dE_0}{dx} \right) \cos \omega t$$  \hspace{1cm} (2.72)

where $dE_0/dx$ is to be evaluated at $x_0$. Averaging (2.72) over time, we get

$$m_s \ddot{x}_0 = q_s \frac{dE_0}{dx} \bigg|_{x_0} \dot{x}_1 \cos \omega t$$ \hspace{1cm} (2.73)

To obtain an equation for $x_1$, we note that $\ddot{x}_1 \gg \ddot{x}_0$ since $x_1$ is high frequency; moreover, in the spirit of the Taylor expansion we have $E_0 \gg x_1(dE_0/dx)$; therefore (2.72) is approximately

$$m_s \ddot{x}_1 = q_s E_0 \cos \omega t$$ \hspace{1cm} (2.74)

with solution $x_1 = -(q_s E_0/m_s \omega^2)(\cos \omega t)$; inserting this in (2.73) and performing the time average one obtains

$$\ddot{x}_0 = -\frac{q_s^2 E_0}{2m_s^2 \omega^2} \frac{dE_0}{dx}$$ \hspace{1cm} (2.75)

so that the ponderomotive force $F_p = m_s \ddot{x}_0$ is

$$F_p = -\frac{q_s^2}{4m_s \omega^2} \frac{d}{dx} (E_0^2)$$ \hspace{1cm} (2.76)

This formula will be easier to remember if we introduce the jitter speed $\tilde{v} = (\ddot{x}_1)_{max} = q_s E_0/m_s \omega$; then

$$F_p = -\frac{m_s}{4} \frac{d}{dx} (\tilde{v}^2)$$ \hspace{1cm} (2.77)

This force is very important in such applications as laser fusion, electron beam fusion, radio frequency heating of tokamaks, radio frequency plugging of mirrors, radio frequency modification of the ionosphere, and solar radio bursts. The study
of the effects of ponderomotive force is one of the areas of current basic plasma physics research. Notice that the overall mass dependence is as given in (2.76), so that the ponderomotive force acts much more strongly on electrons than on ions. A more complete derivation of the ponderomotive force, including the magnetic field in an electromagnetic wave, can be found in Schmidt [4].

2.9 DIFFUSION

We conclude this chapter with a brief discussion of the effects of collisions on the location of the guiding center of a particle in a magnetic field. The discussion of Chapter 1 shows that the effects of many small angle collisions in a plasma are more important than the effects of rare large angle collisions. However, it is simplest to consider here a single large angle collision between two charged particles; the results can then be qualitatively applied to determine the effects of many small angle collisions.

Consider first the head-on collision between two electrons at $x = 0$, as shown in Fig. 2.14. The last gyro-orbit, and the guiding center, of each particle before the collision are indicated in the upper half of the figure. After the collision, electron

![Diagram of head-on collision between two electrons](image)

**Fig. 2.14** Head-on collision between two electrons in a magnetized plasma. Numbers indicate the location of the guiding centers of the two electrons.
number 2 has the same orbit that electron number 1 had before the collision, and vice versa. Thus, the locations of the two guiding centers have been interchanged, and there is no net motion of the electrons. We conclude that collisions between like particles do not lead to diffusion of those particles across magnetic field lines.

Next, consider the (almost) head-on collision between an electron and a slightly more energetic positron at $x = 0$, as shown in Fig. 2.15. The last gyro-orbit and the guiding center of each particle before the collision are indicated in the upper half of the figure. After the collision, the electron has slightly more energy than the positron, and both guiding centers have moved by two gyro-radii in the ($-\hat{z}$)-direction. Thus, the center-of-mass of the system has moved a substantial distance in the ($-\hat{z}$)-direction. We conclude that collisions between unlike particles can cause significant diffusion of particles across magnetic field lines. Further discussion of diffusion can be found in Ref. [1].

This completes our discussion of single-particle motion in prescribed electric and magnetic fields. In the next chapter, we begin a systematic treatment of plasma physics in which the electromagnetic fields and the particle orbits are determined self-consistently.

REFERENCES

PROBLEMS

2.1 Example of a Drift

(a) Consider a particle of charge $q$ and mass $m$, initially at rest at $(x, y, z) = (0, 0, 0)$, in the presence of a static magnetic field $B = B_0 \hat{z}$ and $E = E_0 \hat{y}$. Taking $E_0, B_0 > 0$, sketch the orbit of the particle when $q > 0$.
(b) Derive an exact expression for the orbit $[x(t), y(t), z(t)]$ of the particle in part (a). Does this result agree with the sketch of part (a)?
(c) Show that the orbit in (b) can be separated into an oscillatory term and a constant drift term. After averaging in time over the oscillatory motion, is there any net acceleration? If not, how are the forces in the problem balanced?
(d) In what direction is the drift for $q > 0$? For $q < 0$? If there were many particles of various charges and masses present, would there be any net current?
(e) Suppose the electric field were replaced by a force $F_0$ in the $\hat{y}$-direction. What would be the drift velocity? [Hint: Guess the answer using the last part of (c).]

2.2 Grad-B Drift

Let us derive the grad-B drift in a different way. With the force equation $F = (q/c)v \times B$, insert the zero order orbit and the Taylor expanded magnetic field. Average $F$ over one gyroperiod to obtain an average force. Insert this average force into the general drift equation (2.8), and compare the resulting drift to the grad-B drift (2.28).

2.3 Polarization Drift

Let us get the polarization drift (2.41) in a faster but less rigorous manner. With the given electric field $E = -\dot{E}t \hat{y}$, calculate an $E \times B$ drift. Relate the resulting
accelerated drift to a force (being careful with signs), plug in the $F \times B$ formula (2.8), and compare the result to (2.41).

2.4 Mirror Machines

(a) A mirror machine has mirror ratio 2. A Maxwellian group of electrons is released at the center of the machine. In the absence of collisions, what fraction of these electrons is confined?

(b) Suppose the mirror machine has initially equal densities $n \approx 10^{13}$ cm$^{-3}$ of electrons and protons, each Maxwellian with a temperature $1$ keV $\approx 10^7$ °C. The machine is roughly one meter in size in both directions. Recalling our discussion of collisions from Chapter 1, estimate very roughly the time for

1. loss of the unconfined electrons;
2. loss of the unconfined ions;
3. loss of many of the initially confined electrons (due primarily to which kind of collision?); why do not all of the electrons leave?;
4. loss of the initially confined ions (due primarily to which kind of collision?).

For fusion purposes (supposing the protons were replaced by deuterium or tritium) which of these numbers is the most relevant?

2.5 Drift Energy

A particle of mass $m$ and charge $q$ in a uniform magnetic field $B = B_0 \hat{z}$ is set into motion in the $\hat{x}$-direction by an electric field $E(t) \hat{y}$ that varies slowly from zero to a final value $E_0$. Thus, at the final time the particle has an $E \times B$ drift $v_\theta$.

(a) Use energy arguments to show that the particle’s guiding center must have been displaced a distance $v_\theta \Omega$ in the direction of the electric field.

(b) Integrate the polarization drift velocity from time zero to time infinity to obtain a displacement. Does the answer agree with (a)?
CHAPTER 3

Plasma Kinetic Theory I: Klimontovich Equation

3.1 INTRODUCTION

In this chapter, we begin a study of the basic equations of plasma physics. The word “kinetic” means “pertaining to motion,” so that plasma kinetic theory is the theory of plasma taking into account the motions of all of the particles. This can be done in an exact way, using the Klimontovich equation of the present chapter or the Liouville equation of the next chapter. However, we are usually not interested in the exact motion of all of the particles in a plasma, but rather in certain average or approximate characteristics. Thus, the greatest usefulness of the exact Klimontovich and Liouville equations is as starting points for the derivation of approximate equations that describe the average properties of a plasma.

In classical plasma physics, we think of the particles as point particles, each with a given charge and mass. Suppose we have a gas consisting of only one particle. This particle has an orbit $X_i(t)$ in three-dimensional configuration space $x$. The orbit $X_i(t)$ is the set of positions $x$ occupied by the particle at successive times $t$. Likewise, the particle has an orbit $V_i(t)$ in three-dimensional velocity space $v$. We combine three-dimensional configuration space $x$ and three-dimensional velocity space $v$ into six-dimensional phase space $(x,v)$. The density of one particle in this phase space is

$$N(x,v,t) = \delta[x - X_i(t)]\delta[v - V_i(t)]$$  \hspace{1cm} (3.1)

where $\delta[x - X_i] \equiv \delta(x - X_i)\delta(y - Y_i)\delta(z - Z_i)$, etc. (The properties of the Dirac delta function are reviewed in Ref. [1], p. 29, and in Ref. [2], pp. 53–54.) Note that $X_i, V_i$ are the Lagrangian coordinates of the particle itself, whereas $x, v$ are the Eulerian coordinates of the phase space.
EXERCISE  At any time $t$, the density of particles integrated over all phase space must yield the total number of particles in the system. Verify this for the density (3.1).

Next, suppose we have a system with two point particles, with respective orbits $[X_1(t), V_1(t)]$ and $[X_2(t), V_2(t)]$ in phase space $(x,v)$. By analogy to (3.1), the particle density is

$$N(x,v,t) = \sum_{i=1}^{2} \delta(x - X_i(t)) \delta(v - V_i(t)) \quad (3.2)$$

EXERCISE  Repeat the previous exercise for (3.2).

Now suppose that a system contains two species of particles, electrons and ions, and each species has $N_0$ particles. Then the density $N_s$ of species $s$ is

$$N_s(x,v,t) = \sum_{i=1}^{N_0} \delta(x - X_i(t)) \delta(v - V_i(t)) \quad (3.3)$$

and the total density $N$ is

$$N(x,v,t) = \sum_{s \in e,i} N_s(x,v,t) \quad (3.4)$$

EXERCISE  Repeat the previous exercise for (3.4).

If we know the exact positions and velocities of the particles at one time, then we know them at all later times. This can be seen as follows. The position $X_i(t)$ of particle $i$ satisfies the equation

$$\dot{X}_i(t) = V_i(t) \quad (3.5)$$

where an overdot means a time derivative. Likewise, the velocity $V_i(t)$ of particle $i$ satisfies the Lorentz force equation

$$m_s \ddot{V}_i(t) = q_i E^m[X_i(t),t] + \frac{q_s}{c} V_i(t) \times B^m[X_i(t),t] \quad (3.6)$$

where the superscript $m$ indicates that the electric and magnetic fields are the microscopic fields self-consistently produced by the point particles themselves, together with externally applied fields. [On the right of (3.6), the portion of $E^m$ and $B^m$ produced by particle $i$ itself is deleted.] The microscopic fields satisfy Maxwell's equations

$$\nabla \cdot E^m(x,t) = 4\pi \rho^m(x,t) \quad (3.7)$$

$$\nabla \cdot B^m(x,t) = 0 \quad (3.8)$$

$$\nabla \times E^m(x,t) = -\frac{1}{c} \frac{\partial B^m(x,t)}{\partial t} \quad (3.9)$$

and

$$\nabla \times B^m(x,t) = \frac{4\pi}{c} J^m(x,t) + \frac{1}{c} \frac{\partial E^m(x,t)}{\partial t} \quad (3.10)$$
The microscopic charge density is

$$\rho^m(x,t) = \sum_{e,i} q_s \int dv N_s(x,v,t)$$  \hspace{1cm} (3.11)

while the microscopic current is

$$J^m(x,t) = \sum_{e,i} q_s \int dv \nabla N_s(x,v,t)$$  \hspace{1cm} (3.12)

**EXERCISE** Convince yourself that (3.11) and (3.12) yield the correct charge density and current.

Equations 3.7 to 3.12 determine the exact fields in terms of the exact particle orbits, while (3.5) and (3.6) determine the exact particle orbits in terms of the exact fields. The entire set of equations is closed, so that if the positions and velocities of all particles, and the fields, are known exactly at one time, then they are known exactly at all later times.

### 3.2 KLIMONTOVICH EQUATION

An exact equation for the evolution of a plasma is obtained by taking the time derivative of the density $N_s$. From (3.3), this is

$$\frac{\partial N_s(x,v,t)}{\partial t} = - \sum_{i=1}^{N_0} \dot{X}_i \cdot \nabla_x \delta[x - X_i(t)] \delta[v - V_i(t)]$$

$$- \sum_{i=1}^{N_0} \dot{V}_i \cdot \nabla_v \delta[x - X_i(t)] \delta[v - V_i(t)]$$  \hspace{1cm} (3.13)

where we have used the relations

$$\frac{\partial}{\partial a} f(a - b) = - \frac{\partial}{\partial b} f(a - b)$$

and

$$\frac{d}{dt} f[g(t)] = \frac{df}{dg} \dot{g}$$

and where $\nabla_x \equiv (\partial_x, \partial_y, \partial_z)$ and $\nabla_v \equiv (\partial_v_x, \partial_v_y, \partial_v_z)$. Using (3.5) and (3.6), we can write $\dot{X}_i$ and $\dot{V}_i$ in terms of $V_i$ and the fields $E^m$ and $B^m$, whereupon (3.13) becomes

$$\frac{\partial N_s(x,v,t)}{\partial t} = - \sum_{i=1}^{N_0} V_i \cdot \nabla_x \delta[x - X_i] \delta[v - V_i]$$

$$- \sum_{i=1}^{N_0} \left\{ \frac{q_s}{m_s} E^m[X_i(t),t] + \frac{q_s}{m_s} c \times B^m[X_i(t),t] \right\} \cdot \nabla_v \delta[x - X_i] \delta[v - V_i]$$  \hspace{1cm} (3.14)

An important property of the Dirac delta function is

$$a \delta(a - b) = b \delta(a - b)$$

**EXERCISE** How would one prove this relation?
This relation allows us to replace $V(t)$ with $v$, and $X(t)$ with $x$, on the right of (3.14) (but not in the arguments of the delta functions) so that (3.14) becomes

$$\frac{\partial N_i(x,v,t)}{\partial t} = -v \cdot \nabla_v \sum_{i=1}^{N_i} \delta(x - X_i)[v - V_i]$$

$$- \left[ \frac{q_i}{m_e} E^m(x,t) + \frac{q_i}{m_e c} v \times B^m(x,t) \right] \cdot \nabla_v \sum_{i=1}^{N_i} \delta(x - X_i)[v - V_i]$$

(3.15)

But the two summations on the right of (3.15) are just the density (3.3); therefore

$$\frac{\partial N_s(x,v,t)}{\partial t} + v \cdot \nabla_v N_s + \frac{q_s}{m_s} \left( E^m + \frac{v}{c} \times B^m \right) \cdot \nabla_v N_s = 0$$

(3.16)

This is the exact Klimontovich equation (Klimontovich [3]; Dupree [4]).

The Klimontovich equation, together with Maxwell’s equations, constitute an exact description of a plasma. Given the initial positions and velocities of the particles, the initial densities $N_i(x,v,t = 0)$ and $N_s(x,v,t = 0)$ are given exactly by (3.3). The initial fields are then chosen to be consistent with Maxwell’s equations (3.7) to (3.12). With these initial conditions the problem is completely deterministic, and the densities and fields are exactly determined for all time.

In practice, we never carry out this procedure. The Klimontovich equation contains every one of the exact single particle orbits. This is far more information than we want or need. What we really want is information about certain average properties of the plasma. We do not really care about all of the individual electromagnetic fields contributed by the individual charges. What we do care about is the average long-range electric field, which might exist over many thousands or millions of interparticle spacings. The usefulness of the Klimontovich equation comes from its role as a starting point in the derivation of equations that describe the average properties of a plasma.

The Klimontovich equation can be thought of as expressing the incompressibility of the “substance” $N_i(x,v,t)$ as it moves about in the $(x,v)$ phase space. (Is it any wonder that a point particle is incompressible?) This can be seen as follows. Imagine a hypothetical particle with charge $q_s$, mass $m_s$, which at time $t$ finds itself at the position $(x,v)$. This hypothetical particle has an orbit in phase space determined by the fields in the system. Imagine taking a time derivative of any quantity along this orbit (such a time derivative is called a convective derivative). This derivative must include the time variation produced by the changing position in $(x,v)$ space as well as the explicit time variation of the quantity. Thus, it must be given by

$$\frac{D}{Dt} = \frac{\partial}{\partial t} + \left. \frac{dx}{dt} \right|_{\text{orbit}} \cdot \nabla_x + \left. \frac{dv}{dt} \right|_{\text{orbit}} \cdot \nabla_v$$

(3.17)

where by $dx/dt|_{\text{orbit}}$ we mean the change in position $x$ of the hypothetical particle with time; likewise for $dv/dt|_{\text{orbit}}$. But for our hypothetical particle at position $(x,v)$
in phase space we know that
\[
\frac{dx}{dt} \bigg|_{\text{orbit}} = v
\] (3.18)
and
\[
\frac{dv}{dt} \bigg|_{\text{orbit}} = \frac{q_s}{m_s} \left[ E^m(x,t) + \frac{v}{c} \times B^m(x,t) \right]
\] (3.19)
Thus,
\[
\frac{D}{Dt} = \frac{\partial}{\partial t} + v \cdot \nabla_x + \frac{q_s}{m_s} \left[ E^m(x,t) + \frac{v}{c} \times B^m(x,t) \right] \cdot \nabla_v,
\] (3.20)
and the Klimontovich equation (3.16) simply says
\[
\frac{D}{Dt} N_s(x,v,t) = 0
\] (3.21)
The density of particles of species \( s \) is a constant in time, as measured along the orbit of a hypothetical particle of species \( s \). This is true whether we are moving along the orbit of an actual particle, in which case the density is infinite, or whether we are moving along a hypothetical orbit that is not occupied by an actual particle, in which case the density is zero. Note that the density is only constant as measured along orbits of hypothetical particles; in \((x,v)\) space at a given time it is not constant but is zero or infinite.

There is yet a third way to think of the Klimontovich equation. Any fluid in which the fluid density \( f(r,t) \) is neither created nor destroyed satisfies a continuity equation
\[
\partial_t f(r,t) + \nabla_r \cdot (f \mathbf{V}) = 0
\] (3.22)
where \( \nabla_r \) is the divergence vector in the phase space under consideration, and \( \mathbf{V} \) is a vector that gives the time rate of change of a fluid element at a point in phase space. (See, for example, Symon [5], p. 317.) In the present case, \( \nabla_r = (\nabla_x, \nabla_v) \) and \( \mathbf{V} = (dx/dt|_{\text{orbit}}, dv/dt|_{\text{orbit}}) \). Since the particle density is neither created nor destroyed, it must satisfy a continuity equation of the form
\[
\partial_t N_s(x,v,t) + \nabla_x \cdot (v N_s) + \nabla_v \cdot \left\{ \frac{q_s}{m_s} \left[ E^m + \frac{v}{c} \times B^m \right] N_s \right\} = 0
\] (3.23)
It is left as a problem to demonstrate that the continuity equation (3.23) is equivalent to the Klimontovich equation (3.16).

### 3.3 PLASMA KINETIC EQUATION

Although the Klimontovich equation is exact, we are really not interested in exact solutions of it. These would contain all of the particle orbits, and would thus be far too detailed for any practical purpose. What we really would like to know are the average properties of a plasma. The Klimontovich equation tells us whether or not a particle with infinite density is to be found at a given point \((x,v)\) in phase space.
What we really want to know is how many particles are likely to be found in a small volume \( \Delta x \Delta v \) of phase space whose center is at \((x,v)\). Thus, we really are not interested in the spikey function \( N_s(x,v,t) \), but rather in the smooth function
\[
f_s(x,v,t) \equiv \langle N_s(x,v,t) \rangle
\]
(3.24)

The most rigorous way to interpret \( \langle \cdot \rangle \) is as an ensemble average [6] over an infinite number of realizations of the plasma, prepared according to some prescription. For example, we could prepare an ensemble of equal temperature plasmas, each in thermal equilibrium, and each with a test charge \( q_T \) at the origin of configuration space. The resulting \( f_s \) and \( f_i \) would then be consistent with the discussion of Debye shielding in Section 1.2.

There is another useful interpretation of the distribution function \( f_s(x,v,t) \), the number of particles of species \( s \) per unit configuration space per unit velocity space. Suppose we are interested in long range electric and magnetic fields that extend over distances much larger than a Debye length. Then we can imagine a box, centered around the point \( x \) in configuration space, of a size much greater than a mean interparticle spacing, but much smaller than a Debye length (this is easy to do in a plasma; why?) We can now count the number of particles of species \( s \) in the box at time \( t \) with velocities in the range \( v \) to \( v + \Delta v \), divide by (the size of the box multiplied by \( \Delta v_x \Delta v_y \Delta v_z \)), and call the result \( f_s(x,v,t) \). This number will of course fluctuate with time but, if there are very many particles in the box, the fluctuations will be tiny and the \( f_s(x,v,t) \) obtained in this manner will agree very well with that obtained in the more rigorous ensemble averaging procedure.

An equation for the time evolution of the distribution function \( f_s(x,v,t) \) can be obtained from the Klimontovich equation (3.16) by ensemble averaging. We define \( \delta N_s \), \( \delta E \), and \( \delta B \) by
\[
N_s(x,v,t) = f_s(x,v,t) + \delta N_s(x,v,t)
\]
\[
E^m(x,v,t) = E(x,v,t) + \delta E(x,v,t)
\]
(3.25)
and
\[
B^m(x,v,t) = B(x,v,t) + \delta B(x,v,t)
\]
where \( B \equiv \langle B^m \rangle \), \( E \equiv \langle E^m \rangle \), and \( \langle \delta N_s \rangle = \langle \delta E \rangle = \langle \delta B \rangle = 0 \). Inserting these definitions into (3.16) and ensemble averaging, we obtain
\[
\begin{align*}
\frac{\partial f_s(x,v,t)}{\partial t} + v \cdot \nabla_x f_s & = \frac{q_s}{m_s} \left( E + \frac{v}{c} \times B \right) \cdot \nabla_v f_s \\
& - \frac{q_s}{m_s} \langle \delta E + \frac{v}{c} \times \delta B \rangle \cdot \nabla_v \langle \delta N_s \rangle
\end{align*}
\]
(3.26)

Equation (3.26) is the exact form of the plasma kinetic equation. We shall meet other forms of this equation in the next chapter.

The left side of (3.26) consists only of terms that vary smoothly in \((x,v)\) space. The right side is the ensemble average of the products of very spikey quantities like \( \delta E = E^m - \langle E^m \rangle \) and \( \delta N_s \). Thus, the left side of (3.26) contains terms that are insensitive to the discrete-particle nature of the plasma, while the right side of (3.26) is very sensitive to the discrete-particle nature of the plasma. But the discrete-particle nature of a plasma is what gives rise to collisional effects, so that
the left side of (3.26) contains smoothly varying functions representing collective effects, while the right side represents the collisional effects. We have seen in Section 1.6 that the ratio of the importance of collisional effects to the importance of collective effects is sometimes given by $1/\Lambda$, which is a very small number. We might guess that for many phenomena in a plasma, the right side of (3.26) has a size $1/\Lambda$ compared to each of the terms on the left side; thus the right side can be neglected for the study of such phenomena. This indeed is the case, as shown in the next two chapters.

This important point can be illustrated by a hypothetical exercise. Imagine that we break each electron into an infinite number of pieces, so that $n_e \to \infty, m_e \to 0$, and $e \to 0$, while $n_0 e = \text{constant}, e/m_e = \text{constant},$ and $v_e = \text{constant}.$

**EXERCISE** Show that in this hypothetical exercise, $\omega_e = \text{constant}, \lambda_e = \text{constant},$ but $T_e \to 0$ and $\Lambda_e \to \infty$.

Then any volume, no matter how small, would contain an infinite number of point particles, each represented by a delta function with infinitesimal charge. Statistical mechanics tells us that the relative fluctuations in such a plasma would vanish, since the fluctuations in the number of particles $N_0$ in a certain volume is proportional to the square root of that number. Thus, on the right side of (3.26) we have $\delta N_s \sim N_s^{1/2} \sim \Lambda_e^{1/2},$ and $\delta E$ and $\delta B,$ which are produced by $\delta N_s$ behaving like (from Poisson’s equation) $\sim e\delta N_s \sim N_0^{-1} N_0^{1/2} \sim N_0^{-1/2} \sim \Lambda_e^{-1/2},$ so that the right side becomes constant. On the left, however, each term becomes infinite as $f_s \to \infty.$ Thus, the relative importance of the right side vanishes $\sim N_0^{-1} \sim \Lambda_e^{-1},$ and we have

\[
\frac{\partial f_s(x,v,t)}{\partial t} + v \cdot \nabla f_s + \frac{q_s}{m_s} \left( E + \frac{v}{c} \times B \right) \cdot \nabla_v f_s = 0
\]

(3.27)

which is the *Vlasov [7] equation* (sometimes referred to as the collisionless Boltzmann equation). This approximate equation, which neglects collisional effects, is often called the most important equation in plasma physics. Its properties will be explored in detail in Chapter 6.

The fields $E$ and $B$ of (3.27) are the ensemble averaged fields of (3.25). They must satisfy the ensemble averaged versions of Maxwell’s equations (3.7) to (3.12), which are

\[
\nabla \cdot E(x,t) = 4\pi \rho
\]

\[
\nabla \cdot B(x,t) = 0
\]

\[
\nabla \times E(x,t) = -\frac{1}{c} \frac{\partial B}{\partial t}
\]

\[
\nabla \times B(x,t) = \frac{4\pi}{c} J + \frac{1}{c} \frac{\partial E}{\partial t}
\]

\[
\rho(x,t) \equiv \langle \rho^m \rangle = \sum_{e,i} q_s \int dv f_s(x,v,t)
\]

and

\[
J(x,t) \equiv \langle J^m \rangle = \sum_{e,i} q_s \int dv v f_s(x,v,t)
\]

(3.28)
In the next two chapters we shall approach the plasma kinetic equation (3.26) from another direction, and shall use approximate methods to evaluate the collisional right side. In Chapter 6 we shall take up the study of the Vlasov equation (3.27).

PROBLEM

3.1 Klimontovich as Continuity

Prove that the continuity equation (3.23) is equivalent to the Klimontovich equation (3.16).
CHAPTER 4

Plasma Kinetic Theory II: Liouville Equation

4.1 INTRODUCTION

In addition to the Klimontovich equation, there is another equation, the Liouville equation, which provides an exact description of a plasma. Like the Klimontovich equation, the Liouville equation is of no direct use, but provides a starting point for the construction of approximate statistical theories. One of the most useful practical results of this approach is to provide us with an approximate form for the right side of the plasma kinetic equation (3.26), which tells us how the distribution function changes in time due to collisions.

The Klimontovich equation describes the behavior of individual particles. By contrast, the Liouville equation describes the behavior of systems. Consider first a “system” consisting of one charged particle. Suppose we measure this particle’s position in a coordinate system $x_i$; then the orbit of the particle $X_i(t)$ is the set of positions $x_i$ occupied by the particle at consecutive times $t$. Likewise, in velocity space we denote the orbit of the particle $V_i(t)$; this is the set of velocities taken by the particle at consecutive times $t$; these velocities are measured in a coordinate system $v_i$. We thus have a phase space $(x_i, v_i) = (x_1, y_1, z_1, v_1, v_2, v_3)$. In this six-dimensional phase space there is one “system” consisting of one particle. The density of systems in this phase space is

$$N(x_i, v_i, t) = \delta(x_i - X_i(t))\delta(v_i - V_i(t))$$  \hspace{1cm} (4.1)

Next, consider a system of two particles. We introduce a set of coordinate axes for each particle. Particle 1 has $(x_1, v_1)$ coordinate axes as before. Particle 2 has $(x_2, v_2)$ coordinate axes that lay right on top of the $(x_1, v_1)$ coordinate axes. The orbit $X_1(t)$, $V_1(t)$ of particle 1 is measured with respect to the $(x_1, v_1)$ coordinate axes, while the orbit $X_2(t)$, $V_2(t)$ of particle 2 is measured with respect to the $(x_2, v_2)$ coordinate...
axes. We now introduce an entirely new phase space, having twelve dimensions. The phase space is

\[ (x_1, v_1, x_2, v_2) = (x_1, y_1, z_1, v_{x_1}, v_{y_1}, v_{z_1}, x_2, y_2, z_2, v_{x_2}, v_{y_2}, v_{z_2}) \]  \( (4.2) \)

In this twelve-dimensional phase space, there is one system that is occupying the point \([x_1 = X_1(t), v_1 = V_1(t), x_2 = X_2(t), v_2 = V_2(t)]\) at time \(t\). The density of systems in this phase space is

\[ N(x_1, v_1, x_2, v_2, t) = \delta[x_1 - X_1(t)]\delta[v_1 - V_1(t)]\delta[x_2 - X_2(t)]\delta[v_2 - V_2(t)] \]  \( (4.3) \)

**EXERCISE** Show that there is indeed one system in the phase space by integrating the density \((4.3)\) over all phase space.

Note that the density \(N\) in \((4.3)\) is completely different from the density \(N_6\), used in the previous chapter in the discussion of the Klimontovich equation. The density \(N_6\) in Ch. 3 is the density of particles in six-dimensional phase space. The density \(N\) in \((4.3)\) is the density of systems (each having two particles) in twelve-dimensional phase space.

Finally, suppose that we have a system of \(N_0\) particles. With each particle \(i, i = 1, 2, \ldots, N_0\), we associate a six-dimensional coordinate system \((x_i, v_i)\). Using these \(6N_0\) coordinate axes, we construct a \(6N_0\)-dimensional phase space, analogous to the twelve-dimensional phase space in \((4.2)\). There is one system in \(6N_0\)-dimensional phase space; therefore the density of systems, by analogy with the density of systems \((4.3)\), is

\[ N(x_1, v_1, x_2, v_2 \ldots x_{N_0}, v_{N_0}, t) = \prod_{i=1}^{N_0} \delta[x_i - X_i(t)]\delta[v_i - V_i(t)] \]  \( (4.4) \)

where \(\prod_{i=1}^{N_0} f_i \equiv f_1 f_2 \ldots f_{N_0}\).

**EXERCISE** Use \((4.4)\) to prove that there is one system in all of phase space.

### 4.2 LIOUVILLE EQUATION

As with the Klimontovich equation in Chapter 3, the Liouville equation is obtained by taking the time derivative of the appropriate density. In this case, we take the time derivative of the density of systems \((4.4)\). Because the density of systems \((4.4)\) is the product of \(6N_0\) terms, its time derivative involves the sum of \(6N_0\) terms. Using the relation

\[ \frac{\partial}{\partial t} \delta[x_i - X_i(t)] = -\frac{\partial X_i}{\partial t} \cdot \nabla x_i \delta[x_i - X_i(t)] \]  \( (4.5) \)

and similar relations encountered in the previous chapter, the time derivative of \((4.4)\) is

\[ \frac{\partial N}{\partial t} + \sum_{i=1}^{N_0} \dot{V}_i(t) \cdot \nabla x_i \cdot \prod_{j=1}^{N_0} \delta(x_j - X_j)\delta(v_j - V_j) \]

\[ + \sum_{i=1}^{N_0} \dot{V}_i \cdot \nabla v_i \cdot \prod_{j=1}^{N_0} \delta(x_j - X_j)\delta(v_j - V_j) = 0 \]  \( (4.6) \)
Using \( a \delta(a - b) = b \delta(a - b) \) to replace \( \mathbf{V}_i \) by \( \mathbf{v}_i \), and similarly for \( \dot{\mathbf{V}}_i \), so that for the remainder of this chapter

\[
\dot{\mathbf{V}}_i(t) = \frac{q_i}{m_i} \left[ \mathbf{E}^n(x_i, t) + \frac{\mathbf{v}_i}{c} \times \mathbf{B}^n(x_i, t) \right]
\]

(4.7)

and noting that the products are just the density of systems \( N \), (4.6) becomes

\[
\frac{\partial N}{\partial t} + \sum_{i=1}^{N_e} \mathbf{v}_i \cdot \nabla x_i N + \sum_{i=1}^{N_i} \dot{\mathbf{V}}_i(t) \cdot \nabla v_i N = 0
\]

(4.8)

which is the Liouville equation. When combined with Maxwell’s equations and the Lorentz force equation, the Liouville equation is an exact description of a plasma. For a two-component plasma with \( N_e/2 \) electrons and \( N_i/2 \) ions, the expression for \( \mathbf{V}_i(t) \) will depend upon whether the \( i \)th particle is an electron or a proton. The Liouville equation has all of the advantages and all of the disadvantages of the Klimontovich equation. Because it contains all of the exact six-dimensional orbits of the individual particles in a single system orbit in \( 6N_0 \)-dimensional space, it contains far more information than we want or need. Its usefulness is as a starting point in deriving a reduced statistical description, which with appropriate approximations can yield practical information.

Equation (4.8) has the form of a convective time derivative in the \( 6N_0 \)-dimensional phase space,

\[
\frac{D}{Dt} N(x_1, v_x, x_2, v_2, \ldots, x_{N_0}, v_{N_0}, t) = 0
\]

(4.9)

where

\[
\frac{D}{Dt} \equiv \frac{\partial}{\partial t} + \sum_{i=1}^{N_0} \mathbf{v}_i \cdot \nabla x_i + \sum_{i=1}^{N_0} \dot{\mathbf{V}}_i(t) \cdot \nabla v_i
\]

(4.10)

Here, \( \dot{\mathbf{V}}_i(t) \) is expressed in terms of the position \( (x_1, v_1, x_2, v_2, \ldots, x_{N_0}, v_{N_0}) \) of the system in \( 6N_0 \)-dimensional phase space, since that position determines the positions of the particles in six-dimensional space and thus the fields at all points in six-dimensional space through Maxwell’s equations. Thus, the convective time derivative, taken along the system orbit in \( 6N_0 \)-dimensional phase space, is zero. The density of systems is incompressible.

The Liouville equation (4.8) can also be put in the form of a continuity equation. Recall the vector identity \( \nabla \cdot (a \mathbf{b}) = \mathbf{b} \cdot \nabla a + a \nabla \cdot \mathbf{b} \). Then

\[
\mathbf{v}_i \cdot \nabla x_i N = \nabla x_i \cdot (v_i N)
\]

(4.11)

since \( \mathbf{v}_i \) and \( x_i \) are independent variables. Similarly,

\[
\dot{\mathbf{V}}_i \cdot \nabla v_i N = \nabla v_i \cdot (\dot{\mathbf{V}}_i N)
\]

(4.12)

since

\[
\nabla v_i \cdot \dot{\mathbf{V}}_i = \nabla v_i \cdot \left\{ \frac{q_i}{m_i} \left[ \mathbf{E}^n(x_i, t) + \frac{\mathbf{v}_i}{c} \times \mathbf{B}^n(x_i, t) \right] \right\} = 0
\]

(4.13)

**EXERCISE** Prove (4.13).
Then the Liouville equation (4.8) becomes

$$\frac{\partial N}{\partial t} + \sum_{i=1}^{N_0} \nabla_{x_i} \cdot (v_i N) + \sum_{i=1}^{N_0} \nabla_{v_i} \cdot (\hat{v}_i N) = 0$$  \hspace{1cm} (4.14)

In the form of a continuity equation, the Liouville equation expresses the conservation of systems in $6N_0$-dimensional phase space.

As we have introduced it, the Liouville equation describes the exact orbit of a single point in $6N_0$-dimensional phase space. An example is shown in Fig. 4.1, which is a projection of the orbit onto three of the $6N_0$ dimensions. As the individual particles of the system move about in six-dimensional space, the system itself moves along a continuous orbit in $6N_0$-dimensional phase space.

Suppose that we have an ensemble of such systems, prepared at time $t_0$. At any later time $t \geq t_0$, we define

$$f_{N_0}(x_1, v_1, x_2, v_2, \ldots, x_{N_0}, v_{N_0}, t) dx_1 dv_1 dx_2 dv_2 \ldots dx_{N_0} dv_{N_0}$$

to be the probability that a particular system is at the point $(x_1, v_1, \ldots, x_{N_0}, v_{N_0})$ in $6N_0$-dimensional phase space, that is, the probability that $x_1(t)$ lies between $x_1$ and $x_1 + dx_1$, and $v_1(t)$ lies between $v_1$ and $v_1 + dv_1$ and $x_3(t)$ lies between $x_3$ and $x_3 + dx_3$, and etc. Since $f_{N_0}$ is a probability density, its integral over all $6N_0$ dimensions must be unity.

Each system in the ensemble moves along an orbit like that shown in Fig. 4.1. We can think of this orbit as carrying its “piece” of probability along with it. A large probability for point $A$ in Fig. 4.1 at time $t_0$ implies a large probability for point $B$ at time $t$. In other words, we can think of the probability density as a fluid moving in the $6N_0$-dimensional phase space. Each element in the probability fluid moves along an exact orbit as given by the solution of the Liouville equation (4.8). Since each element of probability fluid moves along a continuous orbit, and since probability is neither created nor destroyed, the probability fluid must satisfy a

\[ t_0 \]
\[ x_1 \]
\[ v_1 \]
\[ x_2 \]
\[ v_2 \]
\[ x_3 \]
\[ v_3 \]

Fig. 4.1 A projection onto three dimensions of a typical system orbit in $6N_0$-dimensional phase space.
continuity equation in $6N_0$-dimensional phase space of the form (4.14). Thus, $f_{N_0}$ must satisfy

$$\frac{\partial f_{N_0}}{\partial t} + \sum_{i=1}^{N_0} \nabla_{x_i} \cdot (v_i f_{N_0}) + \sum_{i=1}^{N_0} \nabla_{v_i} \cdot (\dot{v}_i f_{N_0}) = 0$$

(4.15)

where $\dot{v}_i(t)$ is, as usual, calculated from the Lorentz force equation (4.7) and the fields $E^n$ and $B^n$ are the exact fields appropriate to the system that occupies this particular point in $6N_0$-dimensional phase space.

We shall only be concerned with smooth functions $f_{N_0}$. Thus, we might think of a drop of ink placed in a glass of water. The initial drop contains all those systems that have a finite probability of being represented in the ensemble of systems at time $t_0$. Ignoring diffusion, the drop may lengthen, contract, distort, squeeze, break into pieces, deform, etc., as time progresses. However, the total volume of ink is always constant; the total probability is always unity. The convection of the probability ink is expressed mathematically by reversing the steps that led from the Liouville equation (4.8) to the continuity equation (4.14). (See Problem 4.1.) Equation (4.15) becomes

$$\frac{\partial f_{N_0}}{\partial t} + \sum_{i=1}^{N_0} v_i \cdot \nabla_{x_i} f_{N_0} + \sum_{i=1}^{N_0} \dot{v}_i \cdot \nabla_{v_i} f_{N_0} = 0$$

(4.16)

which by (4.10) is

$$\frac{Df_{N_0}}{Dt} = 0$$

(4.17)

Equation (4.16) is the Liouville equation for the probability density $f_{N_0}$. Thus, the density of the probability ink is a constant provided that we move with the ink. The probability density $f_{N_0}$ is incompressible.

### 4.3 BBGKY HIERARCHY

As discussed above, the density $f_{N_0}$ represents the joint probability density that particle 1 has coordinates between $(x_1, v_1)$ and $(x_1 + dx_1, v_1 + dv_1)$ and particle 2 has coordinates between $(x_2, v_2)$ and $(x_2 + dx_2, v_2 + dv_2)$, and etc. We may also consider reduced probability distributions

$$f_k(x_1, v_1, x_2, v_2, \ldots, x_k, v_k, t) \equiv V^k \int dx_{k+1} dv_{k+1} \ldots dx_{N_0} dv_{N_0} f_{N_0}$$

(4.18)

which give the joint probability of particles 1 through $k$ having the coordinates $(x_1, v_1)$ to $(x_1 + dx_1, v_1 + dv_1)$ and ... and $(x_k, v_k)$ to $(x_k + dx_k, v_k + dv_k)$, irrespective of the coordinates of particles $k + 1, k + 2, \ldots, N_0$. The factor $V^k$ on the right of (4.18) is a normalization factor, where $V$ is the finite spatial volume in which $f_{N_0}$ is nonzero for all $x_1, x_2, \ldots, x_{N_0}$ (Fig. 4.2). At the end of our theoretical development, we will take the limit $N_0 \to \infty, V \to \infty$, in such a way that $n_0 = N_0/V$ is a constant giving the average number of particles per unit real space. For the present, we assume that $f_{N_0} \to 0$ as $x_i \to \pm \infty$ or $y_i \to \pm \infty$ or $z_i \to \pm \infty$ for any
Fig. 4.2 Finite spatial volume $V$ in which $f_{x_i}$ is nonzero for any $x_i, i = 1, \ldots, N_0$.

$I$. Likewise, because there are no particles with infinite speed, $f_{x_i} \to 0$ as $v_{x_i} \to \pm \infty$ or $v_{y, i} \to \pm \infty$ or $v_{z, i} \to \pm \infty$ for any $i$.

In this development, we do not care which one of the $N_0$ particles is called particle number 1, etc. Thus, we always choose probability densities $f_{x_i}$ that are completely symmetric with respect to the particle labels. For example,

\[
f_{x_i} (\ldots z_7 = 2 \text{ cm} \ldots z_{13} = 5 \text{ cm} \ldots t) = f_{x_i} (\ldots z_7 = 5 \text{ cm} \ldots z_{13} = 2 \text{ cm} \ldots t) \tag{4.19}
\]

provided all of the other independent variables are the same. Here, we must interchange all of the $i = 7$ variables with all of the $i = 13$ variables. This means that when we set $k = 1$ in (4.18), the function $f_i(x, v_i, t)$ is (to within a normalization constant) the number of particles per unit real space per unit velocity space. Thus, this function $f_i(x, v_i, t)$ has the same meaning (to within a normalization constant) as the function $f_i(x, v, t)$ introduced in the previous chapter in connection with the plasma kinetic equation.

To keep the theory as simple as possible, we shall ignore any external electric and magnetic fields. We shall deal with only one species of $N_0$ particles; it is easy enough to generalize the results to a plasma with two species of $N_0/2$ particles each at the end of the development. For some purposes, such as calculating electron-electron collisional effects, the second species can be introduced as a smeared-out ion background of density $n_0$, which simply neutralizes the total electron charge. Finally, we adopt the Coulomb model, which ignores the magnetic fields produced by the charged particle motion. In this model, the acceleration

\[
\dot{V}_i(t) = \sum_{j=1}^{N_0} a_{ij} \tag{4.20}
\]

where

\[
a_{ij} = \frac{q_i^2}{m_i|x_i - x_j|} (x_i - x_j) \tag{4.21}
\]
is the acceleration of particle \( i \) due to the Coulomb electric field of particle \( j \). Since a particle exerts no force on itself, we use (4.21) only if \( i \neq j \); if \( i = j \), we use \( a_{ii} = 0 \). Equation (4.21) replaces Maxwell’s equations and the Lorentz force law. The Liouville equation (4.16) becomes

\[
\frac{\partial f_{N_0}}{\partial t} + \sum_{r=1}^{N_0} v_i \cdot \nabla_{x_r} f_{N_0} + \sum_{j=1}^{N_0} \sum_{i=1}^{N_0} a_{ij} \cdot \nabla_{v_j} f_{N_0} = 0
\]  

(4.22)

Equations for the reduced distributions \( f_{N} \) are obtained by integrating the Liouville equation (4.22) over all \( x_{k+1}, v_{k+1}, x_{k+2}, v_{k+2}, \ldots, x_{N_0}, v_{N_0} \). For example, to obtain the equation for \( f_{N_{r-1}} \) we integrate (4.22) over all \( x_{N_0} \) and \( v_{N_0} \), obtaining

\[
\int dx_{N_0} dv_{N_0} \frac{\partial f_{N_0}}{\partial t} + \int dx_{N_0} dv_{N_0} \sum_{i=1}^{N_0} v_i \cdot \nabla_{x_i} f_{N_0} \\
+ \int dx_{N_0} dv_{N_0} \sum_{i=1}^{N_0} \sum_{j=1}^{N_0} a_{ij} \cdot \nabla_{v_j} f_{N_0} = 0
\]  

(4.23)

Term (1) is easy, since we can move the time derivative outside the integral to obtain

\[
\frac{\partial}{\partial t} \int dx_{N_0} dv_{N_0} f_{N_0} = \nu^{1-N_0} \frac{\partial}{\partial t} f_{N_{r-1}}
\]  

(4.24)

where the definition (4.18) has been used. Term (2) is also easy. In the first \( N_0 - 1 \) terms in the sum, the integration variables are independent of the operator \( v_i \cdot \nabla_{x_i} \); this operator can then be moved outside the integration and we again obtain a term proportional to \( f_{N_{r-1}} \). The last term in the sum, with \( i = N_0 \), is

\[
\int dx_{N_0} dv_{N_0} (v_{x_{N_0}} \partial_{x_{N_0}} + v_{y_{N_0}} \partial_{y_{N_0}} + v_{z_{N_0}} \partial_{z_{N_0}}) f_{N_0} \\
= \int dv_{N_0} dy_{N_0} dz_{N_0} v_{x_{N_0}} f_{N_0} \int_{s_{N_0} = -\infty}^{s_{N_0} = +\infty} + 2 \text{ similar terms}
\]  

(4.25)

since \( f_{N_0} \) vanishes at the boundaries of the system that have been placed at \( x_{N_0} = \pm \infty \), etc. Thus,

\[
\int dv_{N_0} dy_{N_0} dz_{N_0} v_{x_{N_0}} f_{N_0} \int_{s_{N_0} = -\infty}^{s_{N_0} = +\infty} + 2 \text{ similar terms}
\]  

\[
\frac{\partial}{\partial t} \sum_{i=1}^{N_0} v_i \cdot \nabla_{v_i} f_{N_{r-1}}
\]  

(4.26)

Term (3) is not much harder. Splitting the double sum

\[
\sum_{i=1}^{N_0} \sum_{j=1}^{N_0} g_{ij} = \sum_{i=1}^{N_0-1} \sum_{i=1}^{N_0-1} g_{ij} + \sum_{i=1}^{N_0-1} g_{N_0 i} + \sum_{i=1}^{N_0-1} g_{i N_0} + g_{N_0 N_0}
\]

we get
\[ \begin{align*}
\circ &= V^{1-N_0} \sum_{i=1}^{N_e-1} \sum_{j=1}^{N_e-1} a_{ij} \cdot \nabla v_j f_{N_e-1} \\
+ \int dx_{N_0} dv_{N_0} \sum_{j=1}^{N_e-1} a_{N_0,j} \cdot \nabla v_{N_0} f_{N_0} \\
+ \int dx_{N_0} dv_{N_0} \sum_{i=1}^{N_e-1} a_{iN_0} \cdot \nabla v_i f_{N_0}
\end{align*} \] (4.27)

where the \( i = N_0, j = N_0 \) term has been discarded because \( a_{N_0,N_0} = 0 \). The second term on the right vanishes after direct integration with respect to \( dv_{x_{N_0}} \) and evaluation at \( v_{x_{N_0}} = \pm \infty \), etc. The remaining terms in \( \circ, \odot, \) and \( \ominus \), after multiplication by \( V^{N_e-1} \), are

\[ \begin{align*}
\odot &= \frac{\partial}{\partial t} f_{N_e-1} + \sum_{i=1}^{N_e-1} v_i \cdot \nabla x_i f_{N_e-1} + \sum_{j=1}^{N_e-1} \sum_{j=1}^{N_e-1} a_{ij} \cdot \nabla v_j f_{N_e-1} \\
&+ V^{N_e-1} \sum_{i=1}^{N_e-1} \int dx_{N_0} dv_{N_0} a_{iN_0} \cdot \nabla v_i f_{N_0} = 0
\end{align*} \] (4.28)

This is the desired equation for \( f_{N_e-1} \). Notice that it does not depend only on \( f_{N_e-1} \); the last term \( \odot \) depends on \( f_{N_0} \). We have made no approximations in deriving (4.28); within the Coulomb model, it is exact.

Having succeeded in deriving the equation for \( f_{N_e-1} \), let us proceed to derive the equation for \( f_{N_e-2} \). To do this, we integrate (4.28) over all \( x_{N_e-1} \) and over all \( v_{N_e-1} \). As in (4.24), term \( \odot \) yields \( V \partial_t f_{N_e-2} \).

**EXERCISE** Use the definition (4.18) to explain the difference between the power of \( V \) encountered here and that encountered in (4.24).

As in (4.26), term \( \odot \) yields one term that vanishes upon integration, leaving a sum from 1 to \( N_0 - 2 \). In term \( \ominus \), we do as in (4.27); we split the double \( (N_0 - 1) \) sum into a double \( (N_0 - 2) \) sum plus two single \( (N_0 - 2) \) sums, the \( i = N_0 - 1 \), \( j = N_0 - 1 \) term vanishing since \( a_{N_0-1,N_0-1} = 0 \). Term \( \ominus \) becomes

\[ \begin{align*}
\odot &= V \sum_{i=1}^{N_e-2} \sum_{j=1}^{N_e-2} a_{ij} \cdot \nabla v_j f_{N_e-2} \\
+ \int dx_{N_e-1} dv_{N_e-1} \sum_{i=1}^{N_e-2} a_{i,N_e-1} \cdot \nabla v_i f_{N_e-1} \\
+ \int dx_{N_e-1} dv_{N_e-1} \sum_{j=1}^{N_e-2} a_{N_e-1,j} \cdot \nabla v_{N_e-1} f_{N_e-1}
\end{align*} \] (4.29)

The last term on the right vanishes upon direct integration with respect to \( v_{N_e-1} \).
For term (4) we have

\[ (4) = V^{N_0-1} \sum_{i=1}^{N_x-1} \int dx_{N_x-1} \, dv_{N_x-1} \, dx_{N_0} \, dv_{N_0} \, a_{iN_0} \cdot \nabla_v f_{N_0} \]

\[ = V^{N_x-1} \sum_{i=1}^{N_x-2} \int dx_{N_0} \, dv_{N_0} \, a_{iN_0} \cdot \nabla_v \int dx_{N_x-1} \, dv_{N_x-1} \, f_{N_0} \]

(4.30)

where the \( N_0 = 1 \) term in the sum vanishes upon doing the \( dv_{N_x-1} \) integration. The variables \( (x_{N_x}, v_{N_x}) \) and \( (x_{N_x-1}, v_{N_x-1}) \) are simply dummy variables of integration on the far right of (4.30). Therefore, we can switch the labels \( N_0 \) and \( N_0 = 1 \), so that \( a_{iN_0} \) becomes \( a_{iN_x} \). The density \( f_{N_x} \) can stay the same, however, because it has the symmetry property (4.19). Equation (4.30) becomes

\[ (4) = V^{N_x-1} \sum_{i=1}^{N_x-2} \int dx_{N_x-1} \, dv_{N_x-1} \, a_{iN_x-1} \cdot \nabla_v \left( \int dx_{N_0} \, dv_{N_0} \, f_{N_0} \right) \]

\[ = \sum_{i=1}^{N_x-2} \int dx_{N_x-1} \, dv_{N_x-1} \, a_{iN_x-1} \cdot \nabla_v \, f_{N_x-1} \]

(4.31)

which is identical with the middle term on the right of term (3) in (4.29). Collecting all of the remaining terms in (1), (3), (3), and (4) and dividing by \( V \), we obtain

\[ \frac{\partial}{\partial t} f_{N_x-2} + \sum_{i=1}^{N_x-2} v_i \cdot \nabla_x f_{N_x-2} + \sum_{i=1}^{N_x-2} \sum_{j=1}^{N_x-2} a_{ij} \cdot \nabla_v f_{N_x-2} \]

\[ + \frac{2}{V} \sum_{i=1}^{N_x-2} \int dx_{N_x-1} \, dv_{N_x-1} \, a_{iN_x-1} \cdot \nabla_v f_{N_x-1} = 0 \]

(4.32)

This equation for \( f_{N_x-2} \) is quite similar in structure to (4.28) for \( f_{N_x-1} \). Notice again that this equation does not involve only \( f_{N_x-2} \), but also involves \( f_{N_x-1} \) in the last term on the left.

By comparing (4.28) and (4.32), we see a pattern emerging. Using the same manipulations that we have been using (see Problem 4.2), we can generate an equation similar to (4.28) and (4.32) for arbitrary \( k \). This equation is

\[ \frac{\partial}{\partial t} f_k + \sum_{i=1}^{k} v_i \cdot \nabla_x f_k + \sum_{i=1}^{k} \sum_{j=1}^{k} a_{ij} \cdot \nabla_v f_k \]

\[ + \frac{(N_0 - k)}{V} \sum_{i=1}^{k} \int dx_{k+1} \, dv_{k+1} \, a_{i,k+1} \cdot \nabla_v f_{k+1} = 0 \]

(4.33)

for \( k = 1, 2, \ldots, N_0 - 2 \). This is the BBGKY hierarchy (Bogoliubov [1]; Born and Green [2]; Kirkwood [3, 4]; and Yvon [5]). Each equation for \( f_k \) is coupled to the next higher equation through the \( f_{k+1} \) term.

**EXERCISE** Verify that (4.22) for \( f_{N_x} \) and (4.32) for \( f_{N_x-2} \) are in agreement with (4.33). Verify that (4.28) for \( f_{N_x-1} \) is in agreement with (4.33), provided that \( f_{N_x} \) is replaced by \( V^{N_x} f_{N_x} \) in (4.33) [see (4.18)].
As it stands, the BBGKY hierarchy (4.33) is still exact (within the Coulomb model) and is just as hard to solve as the original Liouville equation (4.22). It consists of $N_0$ coupled integro-differential equations. Progress will come only when we take just the first few equations, for $k = 1, k = 2$, etc., and then use an approximation to close the set and cut off the dependence on higher equations.

From (4.33) the $k = 1$ equation is
\[
\partial_t f_1(x_1, v_1, t) + v_1 \cdot \nabla x_1 f_1 + \frac{N_0}{V} \int dx_2 dv_2 a_{12} \cdot \nabla v_1 f_2(x_1, v_1, x_2, v_2, t) = 0
\] (4.34)

This is coupled to the $k = 2$ equation through $f_2$. One way to proceed is to find some approximation for $f_2$ in terms of $f_1$. If we can do this, then (4.34) will be written entirely in terms of $f_1$, and we will have a complete description of the time evolution of $f_1(x_1, v_1, t)$ given the initial value $f_1(x_1, v_1, t = 0)$.

This is a good point at which to repeat our interpretation of the functions $f_1(x_1, v_1, t)$ and $f_2(x_1, v_1, x_2, v_2, t)$. We have said before that $f_1$ is equivalent to $f_i$ in the plasma kinetic equation; when multiplied by $n_0 = N_0/V$, it is the ensemble averaged number of particles per unit real space per unit velocity space at the point $(x_1, v_1)$ in six-dimensional phase space.

**EXERCISE** Use the definition to show that $\int dv_1 f_1(x_1, v_1, t) = 1$ provided that none of the functions $f_k, k = 1, 2, \ldots, N_0$ depend upon the positions $x_1, x_2, \ldots, x_{N_0}$.

We may also say that $f_1(x_1, v_1, t) dx_1 dv_1$ is the probability that a given particle finds itself in the region of phase space between $(x_1, v_1)$ and $(x_1 + dx_1, v_1 + dv_1)$. The interpretation of $f_2$ is similar to the interpretation of $f_1$. The function $f_2$ is the ensemble averaged number of particles per unit $x_1$ real space per unit $x_2$ real space per unit $v_1$ velocity space per unit $v_2$ velocity space. We may also say that $f_2(x_1, v_1, x_2, v_2, t)$ is proportional to the joint probability that particle 1 finds itself at $(x_1, v_1)$ and particle 2 finds itself at $(x_2, v_2)$. Since in this discussion all particles are of the same species, we know that an exact expression for $f_2$ would include the fact that no two particles (electrons, for example) can occupy the same spatial location. Thus, an exact expression for $f_2$ must have the property that $f_2 \to 0$ as $x_1 \to x_2$, regardless of the values of $v_1$ and $v_2$. In developing an approximate expression for $f_2$, we could of course lose this property. Another property that $f_2$ should have is symmetry with respect to the particle labels: $f_2(x_1, v_1, x_2, v_2, t) = f_2(x_2, v_2, x_1, v_1, t)$. This symmetry occurs because the original $f_{N_0}$ has such symmetry, by assumption.

It turns out that $f_2$ has an intimate relation to $f_1$, which can be seen by an elementary example from probability theory. Suppose we have two loaded dice, each of which always rolls a five. Then the probability distribution for the value of the throws of either die is
\[
P_1(x) = \delta(x - 5)
\] (4.35)

The joint probability that the value of the first die will be $x$ and the value of the second die will be $y$ is
\[
P_2(x, y) = \delta(x - 5)\delta(y - 5)
\] (4.36)
But by (4.35) this is just
\[ P_2(x,y) = P_1(x)P_1(y) \]  
(4.37)
This separation always occurs when two quantities are \textit{statistically independent}; that is, the value of one quantity does not depend on the value of the other quantity. Thus, it is always useful in considering joint probability distributions to factor out the piece that would be there if the two quantities were uncorrelated. Thus, for the dice we have
\[ P_2(x,y) = P_1(x)P_1(y) + \delta P(x,y) \]  
(4.38)
where \( \delta P(x,y) = 0 \) by (4.37). For a plasma, we define the \textit{correlation function}
\[ g(x_1,v_1,x_2,v_2,t) \]
by
\[ f_2(x_1,v_1,x_2,v_2,t) = f_1(x_1,v_1,t)f_1(x_2,v_2,t) + g(x_1,v_1,x_2,v_2,t) \]  
(4.39)
This is the first step in the \textit{Mayer} [6] \textit{cluster expansion}.

**EXERCISE** From the definitions of \( f_{N_0} \) and \( f_k \), convince yourself that \( f_2 \) has the same units as \( f_1 \).

We are ready to insert the form (4.39) into the equation (4.34) for \( f_1 \), which becomes
\[ \partial_t f_1(x_1,v_1,t) + v_1 \cdot \nabla_x f_1 + n_0 \int dx_2 dv_2 a_{12} \cdot \nabla_v [f_1(x_1,v_1,t)f_1(x_2,v_2,t) + g(x_1,v_1,x_2,v_2,t)] = 0 \]  
(4.40)
where we have replaced \((N_0 - 1)/V\) by \( n_0 \) because we are interested only in systems with \( N_0 \gg 1 \).

Suppose one assumes that the correlation function vanishes. That is, we assume that the particles in the plasma behave as if they were completely independent of the particular positions and velocities of the other particles. This assumption would be exactly valid if we performed the pulverization procedure discussed in the previous chapter, in which \( n_0 \to \infty, e \to 0, m_e \to 0, \Lambda \to \infty, n_0 e = \text{constant}, e/m_e = \text{constant}, v_e = \text{constant}, \omega_e = \text{constant}, \text{and} \lambda_e = \text{constant}. \) Then each particle would have zero charge, and its presence would not affect any other particle. Collective effects could of course still happen, as these involve only \( f_1 \) and not \( g \). When we set \( g \) equal to zero, (4.40) becomes
\[ \partial_t f_1 + v_1 \cdot \nabla_x f_1 + [n_0 \int dx_2 dv_2 a_{12} f_1(x_2,v_2,t)] \cdot \nabla_v f_1(x_1,v_1,t) = 0 \]  
(4.41)
But the quantity in brackets is just the acceleration \( a_{12} \) produced on particle 1 by particle 2, integrated over the probability distribution \( f_1(x_2,v_2,t) \) of particle 2. This is the ensemble averaged acceleration experienced by particle 1 due to all other particles,
\[ a(x_1,t) \equiv n_0 \int dx_2 dv_2 a_{12} f_1(x_2,v_2,t) \]  
(4.42)

**EXERCISE** Convince yourself that \( a \) is normalized correctly.
Then (4.41) becomes

\[
\partial_t f_i + v_i \cdot \nabla_x f_i + a \cdot \nabla_v f_i = 0
\]  

(4.43)

which we recognize as our old friend the Vlasov equation.

The Vlasov equation is probably the most useful equation in plasma physics, and a large portion of this book is devoted to its study. For our present purposes, however, it is not enough. It does not include the collisional effects that are represented by the two-particle correlation function \( g \). We would like to have at least an approximate equation that does include collisional effects and that, therefore, predicts the temporal evolution of \( f_i \) due to collisions. We must therefore return to the exact \( k = 1 \) equation (4.40) and find some method to evaluate \( g \).

Since \( g \) is defined through (4.39) as \( g = f_2 - f_1 f_1 \), we must go back to the \( k = 2 \) equation in the BBGKY hierarchy in order to obtain an equation for \( f_2 \) and, hence, for \( g \). Setting \( k = 2 \) in (4.33) and using \( (\mathcal{N}_0 - 2)/V \approx n_0 \), one has

\[
\partial_t f_2 + (v_1 \cdot \nabla_x + v_2 \cdot \nabla_x) f_2 + (a_1 \cdot \nabla_v + a_2 \cdot \nabla_v) f_2 + n_0 \int dx_3 \, dv_3 (a_{13} \cdot \nabla_v + a_{23} \cdot \nabla_v) f_3 = 0
\]  

(4.44)

We have seen that it is useful to factor out the part \( f_1 f_1 \) of \( f_2 = f_1 f_1 + g \), which exists when the particles are uncorrelated. Likewise, it is useful to factor from \( f_3 \) the part that would exist when the particles are uncorrelated, plus those parts that result from two-particle correlations. This leads to the next step in the Mayer cluster expansion, which is

\[
f_3(123) = f_i(1)f_i(2)f_i(3) + f_i(1)g(23) + f_i(2)g(13) + f_i(3)g(12) + h(123)
\]  

(4.45)

where we have introduced a simplified notation: \((1) \equiv (x_1, v_1), (2) \equiv (x_2, v_2), \) and \((3) \equiv (x_3, v_3)\). Equation (4.45) will be explored further in Problems 4.4 and 4.5.

Our procedure is to insert (4.45) into (4.44) and neglect \( h(123) \). This means that we neglect three-particle correlations, or three-body collisions. It turns out that these correlations are of higher order in the plasma parameter \( \Lambda \); therefore their neglect is quite well justified for many purposes. The resulting set of equations constitute two equations in two unknowns \( f_i \) and \( g \). Thus, we have truncated the BBGKY hierarchy while retaining the effects of collisions to a good approximation.

Inserting (4.45) for \( f_3 \) and \( f_2 = f_1 f_1 + g \) into the \( k = 2 \) BBGKY equation (4.44), we find for the numbered terms:

\[
\begin{align*}
\text{1} & = \dot{f}_i(1)f_i(2) + \dot{f}_i(2)f_i(1) + g(12) \\
\text{2} & = v_1 \cdot \nabla_x f_i(1)f_i(2) + v_1 \cdot \nabla_x g(12) + \{1 - 2\}
\end{align*}
\]
\[ \Omega = \mathbf{a}_{12} \cdot \nabla_{v_1} f_i(1)f_i(2) + \mathbf{a}_{12} \cdot \nabla_{v_2} g(12) + \{1 \leftrightarrow 2\} \]

\[ \Omega = n_0 \int d^3 \mathbf{a}_{13} \cdot \nabla_{v_1} [f_i(1)f_i(2)f_i(3) + f_i(1)g(23)] \]

\[ + f_i(2)g(13) + f_i(3)g(12)] + \{1 \leftrightarrow 2\} \]

(4.46)

where \( d^3 = dx \, dv_3 \) and \( \{1 \leftrightarrow 2\} \) means that all of the preceding terms on the right side are repeated with the symbols 1 and 2 interchanged. Recall that \( g(12) = g(21) \) by the symmetry of \( f_i \). Many of the terms in (4.46) can be eliminated using the \( k = 1 \) BBGKY equation (4.40). For example,

\[ \Omega + \Omega + \Omega + \Omega = \{\dot{f}_i(1) + v_i \cdot \nabla_{v_i} f_i(1) \]

\[ + n_0 \int d^3 \mathbf{a}_{13} \cdot \nabla_{v_1} [f_i(1)f_i(3) + g(13)]f_i(2) \]

\[ = \text{[left side of (4.40)]} f_i(2) = 0 \]

(4.47)

Term \( \Omega \) likewise combines with three of the \( \{1 \leftrightarrow 2\} \) terms to vanish, leaving

\[
\dot{g}(12) + (v_1 \cdot \nabla_{v_1} + v_2 \cdot \nabla_{v_2})g(12) = \\
- (\mathbf{a}_{12} \cdot \nabla_{v_1} + \mathbf{a}_{13} \cdot \nabla_{v_1})[f_i(1)f_i(2) + g(12)] \\
- \{n_0 \int d^3 \mathbf{a}_{13} \cdot \nabla_{v_1} [f_i(1)g(23) + f_i(3)g(12)] + \{1 \leftrightarrow 2\}\} 
\]

(4.48)

Together with (4.40) which in the condensed notation reads

\[
\dot{f}_i(1) + v_i \cdot \nabla_{v_i} f_i(1) + n_0 \int d^2 \mathbf{a}_{12} \\
\cdot \nabla_{v_i} [f_i(1)f_i(2) + g(12)] = 0 
\]

(4.49)

we have two equations in the two unknowns \( f_i \) and \( g \). We have truncated the BBGKY hierarchy by ignoring three-particle correlations.

In practice, (4.48) and (4.49) are impossibly difficult to solve, either analytically or numerically. They are two coupled nonlinear integro-differential equations in a twelve-dimensional phase space. The present thrust of plasma kinetic theory consists in finding certain approximations to \( g(12) \) that are then inserted in (4.49). Using the definition of the acceleration \( \mathbf{a} \) in (4.42), we rewrite (4.49) as

\[
\dot{f}_i(1) + v_i \cdot \nabla_{v_i} f_i + \mathbf{a} \cdot \nabla_{v_i} f_i = -n_0 \int d^2 \mathbf{a}_{12} \cdot \nabla_{v_i} g(12) 
\]

(4.50)

which is in exactly the same form as the plasma kinetic equation (3.26).

Most of the discussion in this chapter has been exact, in particular, the derivation of the Liouville equation and the BBGKY hierarchy. Even the approximations that lead to (4.48) and (4.49) are extremely good ones, for example, \( 1 \ll N_0 \) and the neglect of three-particle collisions. By contrast, the approximations needed to convert (4.48) and (4.49) into manageable form are sometimes quite drastic and
less justifiable, as will be seen in the next chapter. Further discussion of the Liouville equation and the BBGKY hierarchy can be found in the books of Montgomery and Tidman [7], Montgomery [8], Clemmow and Dougherty [9], Krall and Trivelpiece [10], and Klimontovich [11].

REFERENCES

PROBLEMS

4.1 Continuity vs. Convective

Demonstrate the equivalence between the convective derivative form of the Liouville equation (4.16) and the continuity equation (4.15).

4.2 BBGKY Hierarchy

Integrate (4.32) over all \(x_{N-2}\) and \(v_{N-2}\) to obtain the \(k = N_0 - 3\) equation of the BBGKY hierarchy, and compare your result to (4.33).

4.3 Normalization

Explain in detail the normalization of (4.42).
4.4 Three-Point Correlations (Coins)

In (4.45) we define a three-point joint probability function \( f_3 \) in terms of the one-point probability \( f_1 \), the two-point correlation function \( g \), and the three-point correlation function \( h \). Suppose we apply this kind of thinking to the case of three coins, each of which can come up heads (+) or tails (−). What is the meaning of \( f_3 \) in this case? Write out \( f_3 \) in the form (4.45), and evaluate \( f_3, f_1, g, \) and \( h \) in each of the following cases.

(a) All three coins are "honest," that is, each coin is equally likely to come up heads or tails, and each coin is unaffected by any other coin.
(b) Because the coins are mysteriously locked together, in any one throw all three are heads or tails, the result changing randomly from throw to throw.
(c) All three coins always come up tails.
(d) The first two coins always come up heads, while the third is honest. Note that here the probability functions are not symmetric, so that, for example, \( f_3(1) \) is not the same function as \( f_3(3) \).

4.5 Three-Point Correlations (Dice)

In (4.45) we define a three-point joint probability function \( f_3 \) in terms of the one-point probability \( f_1 \), the two-point correlation function \( g \), and the three-point correlation function \( h \). Suppose we apply this kind of thinking to the case of three dice, each of which can take on integer values from one through six. What is the meaning of \( f_3 \) in this case? Write out \( f_3 \) in the form (4.45), and evaluate \( f_3, f_1, g, \) and \( h \) in each of the following cases.

(a) All three dice are "honest," that is, the value of each die is equally likely one through six and is independent of the value of any other die.
(b) Because the dice are mysteriously locked together, in one throw all three always show the same value, the value changing randomly from throw to throw with all six values equally likely.
(c) All of the dice always come up "five."
(d) The first two dice always come up "two"; the other one is "honest."

4.6 BBGKY Hierarchy

In this chapter, we derive the BBGKY hierarchy from the Liouville equation. This can be done in a completely different way [10], starting with the Klimontovich equation. Explain, by using words and writing equations only for illustration, how the \( k = 1 \) and \( k = 2 \) equations of the BBGKY hierarchy can be obtained from the Klimontovich equation.
CHAPTER 5

Plasma Kinetic Theory III: Lenard–Balescu Equation

5.1 BOGOLIUBOV’S HYPOTHESIS

In the preceding chapter, the BBGKY hierarchy is truncated by neglecting three-particle correlations (three-body collisions). For a good plasma, this is probably a very good approximation, although no rigorous proof exists. The spirit of the approximation is the same as that of Section 1.6, where the collision frequency is calculated as a series of two-body collisions, even though the particle is interacting with $A$ particles simultaneously. Since the collision of particle $A$ with particle $B$ is usually a small angle collision, its effect on the orbit of particle $A$ is small, thus making a negligible effect on the simultaneous collision of particle $A$ with particle $C$.

The result of our truncation of the BBGKY hierarchy is the set of coupled equations (4.48) and (4.50) in the two unknowns $f_1(x_1,v_1,t)$ and $g(x_1,v_1,x_2,v_2,t)$. These equations are quite intractable in general. However, there is one set of simplifying assumptions that is both physically very important and allows the exact (almost) solution of (4.48) and (4.50).

Consider a spatially homogeneous ensemble of plasmas. This means that any function of one spatial variable must be independent of that variable; so $f_1(x_1,v_1,t) = f_1(v_1,t)$ and $a(x_1,t) = a(t) = 0$ by (4.21) and (4.42). Any ensemble averaged function of two spatial variables can only be a function of the difference between those variables; therefore we write $g = g(x_1 - x_2,v_1,v_2,t)$. With these assumptions, (4.50) simplifies considerably and becomes

$$
\partial_t f_1(v_1,t) = - n_0 \int dx_2 \int dv_2 \; a_{12} \cdot \nabla_x \; g(x_1 - x_2,v_1,v_2,t) \tag{5.1}
$$
Equation 4.48 simplifies since two terms are of the form

\[ [n_0 \int d^3 a_{13} f_i(3)] \cdot \nabla_v g(12) = a \cdot \nabla_v g(12) = 0 \]  

(5.2)

leaving

\[ \partial_t g(x_1 - x_2, v_1, v_2, t) + v_1 \cdot \nabla_v g(12) + v_2 \cdot \nabla_v g(12) \]
\[ + (a_{12} \cdot \nabla_v + a_{21} \cdot \nabla_v) g(12) \]
\[ + n_0 \int d^3 a_{13} \cdot \nabla_v f_i(1) g(23) + n_0 \int d^3 a_{23} \cdot \nabla_v f_i(2) g(13) \]
\[ = - (a_{12} \cdot \nabla_v + a_{21} \cdot \nabla_v) f_i(1) f_i(2) \]  

(5.3)

We now wish to argue that the fourth term on the left is smaller than all the other terms and can be discarded. Recall the pulverization procedure of the previous chapter. By that argument, as well as the discussion of collisions in Section 1.6, we argue that the two-point correlation function \( g \) is higher order in the plasma parameter \( \Delta \) than \( f_i \); thus \( g/f_i \sim \Delta^{-1} \). The acceleration \( a_{12} \sim e^2/m_e \sim \Delta^{-1} \) since \( e/m_e \) is constant and \( e \sim n_0^{-1} \sim \Delta^{-1} \); here, we phrase our discussion in terms of electrons. Thus, all terms in (5.3) are \( \sim \Delta^{-1} \) except for the fourth term on the left, which is \( \sim \Delta^{-2} \). We discard this term, leaving

\[ \frac{\partial g(12)}{\partial t} + V_1 g + V_2 g = S \]  

(5.4)

where \( V_1 \) and \( V_2 \) are operators defined by

\[ V_1 g(12) = v_1 \cdot \nabla_v g(12) \]
\[ + [n_0 \int d^3 a_{13} g(23)] \cdot \nabla_v f_i(1) \]  

(5.6)

\[ V_2 g(12) = v_2 \cdot \nabla_v g(12) \]
\[ + [n_0 \int d^3 a_{23} g(13)] \cdot \nabla_v f_i(2) \]  

(5.7)

and the source function \( S \) is

\[ S(x_1 - x_2, v_1, v_2) = - (a_{12} \cdot \nabla_v + a_{21} \cdot \nabla_v) f_i(1) f_i(2) \]  

(5.8)

In this chapter we alternate between the notations (1) and (\( x_1, v_1 \)) depending on convenience. For simplicity, we suppose that we are dealing with an electron plasma. A neutralizing ion background can be thought to be present; it is considered to be smoothed out so that it does not contribute explicitly to the acceleration \( a_{ij} \), which by (4.21) is

\[ a_{ij} = \frac{e^2}{m_e|\mathbf{x}_i - \mathbf{x}_j|^3} (\mathbf{x}_i - \mathbf{x}_j) \]  

(5.9)

The important physical situation to which this discussion applies is as follows. Imagine a beam of electrons incident on a Maxwellian electron plasma in the
\( \mathbf{x} \)-direction. Then the function
\[
F(v_x) \equiv \int dv_y \, dv_z \, f_1(v)
\]  
(5.10)
has the form shown in Fig. 5.1. Ignoring questions of stability (see Chapter 6), we recognize that the beam of electrons represented by the bump at large positive \( v_x \) will experience collisions that will eventually (\( t \to \infty \)) produce a new Maxwellian at a higher temperature. By the discussion of Section 1.6 we can predict the time scale for this process to be \( \sim v_{ce}^{-1} \). The solution of (5.1) and (5.4) which we are about to obtain should yield a very good theoretical description for this important process. This evolution is encountered in such applications as electron beam-pellet fusion and (when generalized to ions) ohmic heating of tokamaks.

The further assumption that allows us to solve the (still very complicated) set of equations (5.1) and (5.4) is Bogoliubov's hypothesis. The assumption is that the two-point correlation function \( g \) relaxes on a time scale very short compared to the time scale on which \( f_1 \) relaxes [1]. Imagine introducing a test electron into a plasma. The other electrons will adjust to the presence of the test electron in roughly the time it takes for them to have a collision with it. With a typical speed \( v_e \) and a typical length \( \lambda_e \), the time for a collision is \( \sim \lambda_e / v_e \sim \omega_e^{-1} \). By contrast, the time for \( f_1 \) to change because of collisions is \( \sim \Delta \omega_e^{-1} \); thus it is indeed quite reasonable to assume that \( g \) relaxes quickly compared to \( f_1 \). Mathematically, we incorporate this assumption by ignoring the time dependence of \( f_1(v_1,t) \) and \( f_1(v_2,t) \) in the source function \( S \) on the right of (5.4). Equation (5.4) is then a linear equation for \( g \) with a known, constant (in time) source function on the right. We can solve such a linear equation for \( g(x_1 - x_2,v_1,v_2,t \to \infty) \) where \( t \to \infty \) is understood to refer to the short time scale on which \( g \) relaxes. The solution for \( g \) will then depend on the factors \( f_1(v_1,t) \) and \( f_1(v_2,t) \) in the source function (5.8). When this solution for \( g \) is substituted into the right side of (5.4), there results a single nonlinear integro-differential equation in the one unknown function \( f_1 \). We

![Fig. 5.1 Distribution \( F(v_x) \) defined in (5.10) for an electron beam incident on a plasma.](image-url)
have finally achieved our goal of truncating the BBGKY hierarchy and have expressed the entire plasma kinetic equation (5.1) in terms of the one unknown function \( f_i(v, t) \).

The implementation of this procedure is straightforward but complicated. In order to understand it, it is useful to have first studied the material in Chapter 6 on the Vlasov equation. Thus, we will not perform the derivation here; it is included in Appendix A. The reader who is studying plasma physics for the first time may wish to accept the results as given here, and proceed to read Appendix A after a thorough study of Chapter 6.

The solution of (5.1) and (5.4) uses the techniques of Fourier transformation in space, Laplace transformation in time, and their inverses. The conventions used in this book are as follows:

\[
\begin{align*}
    f(k) &= \int \frac{dx}{(2\pi)^3} e^{-ik \cdot x} f(x) \\
    f(x) &= \int dk e^{ik \cdot x} f(k) \\
    f(\omega) &= \int_0^\infty dt e^{i\omega t} f(t) \\
    f(t) &= \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{-i\omega t} f(\omega)
\end{align*}
\]  

(5.11) - (5.14)

where the integrals over \( x, k, \) and \( t \) are usually along the real axes while the integral over \( \omega \) is along the Laplace inversion contour to be discussed later.

Expressed in terms of the difference variable \( x = x_1 - x_2 \), the acceleration \( a_{12} \) in (5.9) is

\[
a_{12}(x) = \frac{e^2}{m_e |x|^3} x
\]

(5.15)

with Fourier transform

\[
a_{12}(k) = \frac{-ik}{m_e} \varphi(k)
\]

(5.16)

where

\[
\varphi(k) = \frac{e^2}{2\pi^2 k^2}
\]

(5.17)

is the Fourier transform of the Coulomb potential

\[
\varphi(x) = \frac{e^2}{|x|}
\]

(5.18)

(See Problem 5.1.) Then, as shown in Appendix A, the solution of (5.1) and (5.4), under the Bogoliubov hypothesis, is

\[
\begin{align*}
    \frac{\partial f(v, t)}{\partial t} &= -\frac{8\pi^2 n_0}{m_e^2} \nabla_v \cdot \int dk d\nu \, \frac{\varphi^2(k)}{|e(k, k \cdot v)|^2} \\
    &\times \delta[k \cdot (v - \nu)][f(v)\nabla_v f(v) - f(\nu)\nabla_v f(\nu)]
\end{align*}
\]

(5.19)
which is the *Lenard–Balescu equation* (Refs. [2] to [6]). In this equation, we have dropped the subscript 1 from \(v_1\), and the subscript 1 from \(f_1\), and have used the dielectric function

\[
\varepsilon(k, \omega) = 1 + \frac{\omega_e^2}{k^2} \int dv \frac{k \cdot \nabla_v f(v)}{\omega - k \cdot v}
\]

(5.20)

which will be studied in detail in the next chapter. The velocity integral must be performed along the Landau contour, as discussed in the next chapter. The interpretation of the Lenard–Balescu equation (5.19), and several alternate forms, will be discussed in the next section.

### 5.2 LENARD–BALESCU EQUATION

The Lenard–Balescu equation (5.19) is obtained from the BBGKY hierarchy after several assumptions: three-particle correlations are negligible, the ensemble of plasmas is spatially homogeneous, and the two-particle correlation function \(g\) relaxes much faster than the one-particle distribution function \(f_1\). Thus, the Lenard–Balescu equation is applicable to situations such as the collisional relaxation of a beam in a plasma, but is not applicable in general to the collisional damping of spatially inhomogeneous wave motion or any phenomena that involve high frequencies like \(\omega_e\).

The right side of (5.19) represents the physics of two-particle collisions, since the right side of (5.1) is proportional to the two-particle correlation function \(g\). This is indicated by the factor \(\varepsilon(k)/\varepsilon(k, k \cdot v)\), which appears squared. It will be shown in the next chapter that the dielectric function \(\varepsilon(k, \omega)\) represents the plasma shielding of the field of a test charge. Thus, this term in (5.19) represents the interaction of one particle (together with its shielding cloud) with the potential field of another particle (together with its shielding cloud); that is, the collision of two shielded particles.

There is a problem with the Lenard–Balescu equation (5.19) as it stands. If one converts the \(k\) integration into spherical coordinates, and takes into account the forms (5.17) of \(\omega(k)\) and (5.20) of \(\varepsilon(k, \omega)\), one finds that at large \(k\) the integral diverges like \(\int dk/k \sim \ln k\). Thus, just as in the derivation of the collision frequency in Section 1.6, we find a logarithmic divergence at large \(k\), or small distances. In Section 1.6 we cut off the spatial integral at the lower limit \(p_0\), where \(p_0\) is the impact parameter for large angle collisions. It is argued in Section 1.6 that the physical formulation is not valid for large angle collisions, thus producing an unphysical divergence at short distances. The same thing is going on here. The derivation of the Lenard–Balescu equation is based on the assumption that in the expression

\[
f_2(12) = f_1(1) f_1(2) + g(12)
\]

(5.21)

we have \(|g| \ll |f_1 f_1|\). This assumption led us to discard a term in (5.3) to obtain (5.4). However, this assumption is not always valid. It is not possible for two electrons to get very close to each other; therefore, we must have \(f_2 \to 0\) as \(x_1 \to x_2\), which implies \(g = - f_1 f_1\). Thus, for small values of \(|x_1 - x_2|\) (large \(k\)), it is not correct to assume \(|g| \ll |f_1 f_1|\). In practice, since the divergence is
logarithmic, we can simply cut off the integral in (5.19) at some upper limit wave number corresponding to some lower limit spatial scale. For this purpose, the impact parameter (Landau length) \( p_0 \) for large angle collisions (see Section 1.6) would be a reasonable choice.

The Lenard-Balescu equation (5.19) has several desirable features [4–5]. These are:

- (a) If \( f \geq 0 \) at \( t = 0 \), \( f \geq 0 \) at all \( t \).
- (b) Particles are conserved: \( \frac{d}{dt} \int dv f(v,t) = 0 \).
- (c) Momentum is conserved: \( \frac{d}{dt} \int dv v f(v,t) = 0 \).
- (d) Kinetic energy is conserved: \( \frac{d}{dt} \int dv v^2 f(v,t) = 0 \).
- (e) Any Maxwellian is a time-independent solution.
- (f) As \( t \to \infty \), any \( f \) satisfying (a) approaches a Maxwellian.

A simplified but fairly accurate form of the Lenard-Balescu equation (5.19) can be obtained as follows. We rewrite (5.19) in the form

\[
\frac{\partial f(v,t)}{\partial t} = - \nabla_v \cdot \int dv' \vec{Q}(v,v') \cdot (\nabla_v - \nabla_v) f(v) f(v')
\] (5.22)

with the tensor

\[
\vec{Q}(v,v') = - \frac{8\pi^2 n_0}{m_e^2} \int dk \frac{kk\varphi^2(k)}{|e(k,k \cdot v)|^2} \delta[k \cdot (v - v')]
\]

\[
= - \frac{2n_0 e^4}{m_e^2} \int dk \frac{kk}{k^4} \frac{\delta[k \cdot (v - v')]}{\left|1 + \frac{\psi}{k^2 \lambda_e^2}\right|^2}
\] (5.23)

where the definition (5.17) has been used, and where the dimensionless function \( \psi \) is found from (5.20) to be

\[
\psi(k,k \cdot v) = \nu_e^2 \int dv' \frac{k \cdot \nabla_v f(v')}{k \cdot (v - v')}
\] (5.24)

Again, the velocity integral must be performed along the Landau contour, as discussed in the next chapter. The wave number integral in (5.23) is performed as follows. When we orient the \( \hat{k}_1 \) axis in the \( v - v' \) direction, the \( Q_{ij} \) component of the tensor \( \vec{Q} \) is

\[
Q_{ij}(v,v') = - \frac{2n_0 e^4}{m_e^2} \int dk_1 dk_2 dk_3 \frac{k_i k_j}{k^4} \frac{1}{|v - v'|} \frac{\delta(k)}{\left|1 + \frac{\psi}{k^2 \lambda_e^2}\right|^2}
\] (5.25)

The factor \( \delta(k) \) implies \( Q_{ij} = 0 \) if either \( i = 1 \) or \( j = 1 \). The \( k_1 \) integration is trivially performed using this factor. In cylindrical coordinates with \( k_2 = k \cos \theta, k_3 = k \sin \theta \), and cutting off the integration at an upper wave number \( k_0 = p_0^{-1} \), we find, using \( Q_{33} \) as an example,

\[
Q_{33}(v,v') = - \frac{2n_0 e^4}{m_e^2 |v - v'|} \int_0^{2\pi} d\theta \sin^2 \theta \int_0^{k_0} \frac{dk}{k} \frac{1}{\left|1 + \frac{\psi}{k^2 \lambda_e^2}\right|^2}
\] (5.26)

Since \( \psi \) is a function of \( \theta \) but not of \( k \) [see (5.24)], the wave number integration can be performed (Problem 5.3). The result is
\[ Q_{33}(v,v') = - \frac{n_0 e^4}{m_e^2 |v - v'|} \int_0^{2\pi} d\theta \frac{\text{Im}[\psi \ln(1 + k_0^2 \lambda_v^2/\psi)]}{\text{Im}(\psi)} \sin^2 \theta \] (5.27)

It turns out (as can be seen more clearly after a study of the following chapter) that the dimensionless function \( \psi \) is of order unity. In addition, we recognize the factor \( k_0 \lambda_v = \lambda_v/p_0 \) from Section 1.6 to be (within factors of order unity) the plasma parameter \( \Lambda \). Thus, we neglect unity compared to \( k_0^2 \lambda_v^2/\psi \), and \( \ln(\psi) \) compared to \( \ln(k_0^2 \lambda_v^2) \approx \ln(\Lambda^2) = 2 \ln \Lambda \), to obtain

\[ Q_{33}(v,v') = Q_{22}(v,v') = - \frac{2\pi n_0 e^4}{m_e^2 |v - v'|} \ln \Lambda \] (5.28)

Similar arguments yield \( Q_{23} = Q_{32} = 0 \). A tensor with only the \( Q_{22} \) and \( Q_{33} \) components nonzero can be conveniently expressed in terms of the unit tensor \( \hat{\mathbf{I}} = k_1 k_1 + k_2 k_2 + k_3 k_3 \), with \( g \equiv v - v' \) and recalling that \( \hat{k}_1 = \hat{g} \), we have

\[ \tilde{\mathbf{Q}}(v,v') = - \frac{2\pi n_0 e^4}{m_e^2} \ln \Lambda \frac{g^2 \hat{\mathbf{I}} - gg}{g^3} \] (5.29)

This expression is known as the Landau form for \( \tilde{\mathbf{Q}} \).

With \( \tilde{\mathbf{Q}} \) in the form (5.29), it is possible to put the Lenard-Balescu equation (5.22) in the form of a Fokker-Planck equation. The general Fokker-Planck equation is a very important equation in all aspects of statistical physics, and is derived from first principles in Appendix B. Following Montgomery and Tidman [5], we notice that

\[ \nabla_v \nabla_v g = \frac{g^2}{g^3} \hat{\mathbf{I}} - gg \] (5.30)

so that with an integration by parts (5.22) becomes

\[
\begin{align*}
\partial_t f(v,t) &= \frac{2\pi n_0 e^4 \ln \Lambda}{m_e^2} \nabla_v \cdot [(\nabla_v f) \cdot \nabla_v \nabla_v \int dv' g f(v')] \\
&\quad - f(v) \int dv' \nabla_v (\nabla_v \cdot \nabla_v) g f(v') \\
&\quad = \frac{2\pi n_0 e^4 \ln \Lambda}{m_e^2} \{ \nabla_v \nabla_v \cdot [f(v) \nabla_v \nabla_v \int dv' g f(v')] \\
&\quad - 2 \nabla_v \cdot [f(v) \int dv' \nabla_v (\nabla_v \cdot \nabla_v) g f(v')] \} \\
&\quad = \frac{2\pi n_0 e^4 \ln \Lambda}{m_e^2} \left\{ - 4 \nabla_v \cdot \left[f(v) \nabla_v \int dv' \frac{f(v')}{g} \right] \right\} \\
&\quad + \nabla_v \nabla_v \cdot [f(v) \nabla_v \nabla_v \int dv' g f(v')] \\
&\quad \text{where in the first step we have used } \nabla_v g = - \nabla_v g, \text{ and in the third step we have used } (\nabla_v \cdot \nabla_v) g = 2/g. \text{ This is in the standard form of a Fokker-Planck equation (see Appendix B),}
\end{align*}
\] (5.31)

\[ \frac{\partial f(v,t)}{\partial t} = - \nabla_v \cdot [A f(v)] + \frac{1}{2} \nabla_v \nabla_v : [\tilde{\mathbf{B}} f(v)] \] (5.32)
where the \textit{coefficient of dynamic friction}
\[ A(v, t) = \frac{8\pi n_e e^4}{m_e^2} \ln \frac{\Lambda}{v} \nabla_v \frac{f(v', t)}{|v - v'|} \] (5.33)
and the \textit{diffusion coefficient}
\[ \bar{B}(v, t) = \frac{4\pi n_e e^4}{m_e^2} \nabla_v \nabla_v \int dv' |v - v'| f(v', t) \] (5.34)

With the coefficients (5.33) and (5.34), Eq. (5.32) is known as the \textit{Landau form} of the Fokker–Planck equation.

The meaning of the terms in the Fokker–Planck equation is discussed in Appendix B. The coefficient of dynamic friction $A$ represents the slowing down of a typical particle because of many small angle collisions. The diffusion coefficient represents the increase of a typical particle’s velocity (in the direction perpendicular to its instantaneous velocity) because of many small angle collisions. Thus, the two terms on the right side of the Fokker–Planck equation (5.32) tend to balance each other. They are in perfect balance when $f$ is a Maxwellian, as shown in Problem 5.5.

The Landau form of the Fokker–Planck equation (5.32) has been solved numerically by MacDonald et al. [7] (Fig. 5.2). The initial distribution function $f(v, t = 0) = f(|v|, t = 0)$ is spherically symmetric in velocity space. Figure 5.2 shows the steady progression of the distribution, as time increases, toward a Maxwellian. At late times, there is an overshoot at low speeds, which indicates that it

Fig. 5.2 Time evolution of a spherically symmetric electron distribution function as obtained from a numerical solution of the Landau form of the Fokker–Planck equation (5.32) by MacDonald et al. [7].
takes a long time to populate the high speed tail of the Maxwellian. (Remember that Coulomb collisions become quite weak for fast particles.)

There exist even simpler forms of the Fokker-Planck equation [4] but these are not too accurate and are used only to get a rough idea of collisional effects. One is

$$\frac{\partial f}{\partial t} = v \cdot \nabla f - (v - v_0) f + v^2 \nabla f$$

(5.35)

where $v$ is a collision frequency, and $v_0$ is a constant velocity. An even cruder model, which is not related to the development of the present chapter, is the Krook model,

$$\frac{\partial f}{\partial t} = - v(f - f_0)$$

(5.36)

where $f_0$ is the appropriate Maxwellian distribution. Equation (5.36) is also called the BGK equation, after Bhatnagar, Gross, and Krook [8].

This brings us to the end of our study of plasma kinetic theory including the effects of two-body collisions. The material in this chapter can be truly appreciated only after a careful study of Appendices A and B. However, Appendix A itself can best be understood after one has mastered the treatment of the Vlasov equation, to which we turn our attention in the next chapter.

PROBLEMS

5.1 Fourier Transforms

Find the Fourier transforms (5.16) and (5.17). (Hint: Use spherical polar coordinates with $k \cdot x = kr \cos \theta$.)
5.2 Lenard-Balescu Equation

After referring to Clemmow and Dougherty [4], and Montgomery and Tidman [5], sketch the proofs of properties (a) to (f) of the Lenard-Balescu equation as listed below (5.21).

5.3 An Integral

With the help of a table of integrals, perform the integration in (5.26).

5.4 Simpler Derivation of the Landau Form

The development of the Landau form for $\bar{Q}$, from (5.23) to (5.28), is the standard one. However, a simpler one exists. In (5.23), replace $\epsilon$ by unity, and cut off the wave number integration at a lower wave number $\lambda r^{-1}$ as well as at the upper wave number $p r^{-1}$. Show that (5.28) results. The replacement of $\epsilon$ by unity is equivalent to ignoring the shielding, as can be seen in (5.20).

5.5 Maxwellian

Show that a Maxwellian is an exact time-independent solution of both the Lenard-Balescu equation (5.19) and the Landau form of the Fokker-Planck equation (5.32).

5.6 Two-Point Correlation Function

Discuss the meaning of $f_2 = f_1 f_1 + g$. Why should $g$ depend on $f_1$? In particular, how would $g$ change as we turn up the temperature of a Maxwellian?

5.7 Plasmas and Brownian Motion

Discuss the analogy between collisional effects on a particle in a plasma and Brownian motion. Explain why the collisional effects can be described by a Fokker-Planck equation. Thus, using only words, explain how we could use the results of Section 1.6 on collisions to obtain the Fokker-Planck equation directly, without starting from Liouville $\rightarrow$ BBGKY $\rightarrow$ Lenard-Balescu $\rightarrow$ Fokker-Planck. This is actually the technique used by Rosenbluth et al. [9].

5.8 Units

Check all of the units in (5.19) to (5.36). Using crude dimensional arguments, derive the model (5.35) from the Fokker-Planck equation (5.32) and the coefficients (5.33) and (5.34).
CHAPTER 6
Vlasov Equation

6.1 INTRODUCTION

Possibly the single most important equation in plasma physics is the Vlasov equation. This equation describes the evolution of the distribution function \( f_s(x,v,t) \) in six-dimensional phase space. As discussed in Chapter 3, the distribution function \( f_s(x,v,t) \) can be thought of as the ensemble averaged number of point particles per unit six-dimensional phase space. It can also be thought of as the number of particles at any given time \( t \), in a small region of the six-dimensional phase space of a single plasma, divided by the volume of the small region of six-dimensional phase space. As discussed in Chapter 3, the Vlasov equation becomes exact in the limit that the number of particles \( \Delta \) in a Debye cube becomes infinite.

The Vlasov equation arises naturally from the Klimontovich equation (Chapter 3) or from the BBGKY hierarchy (Chapter 4) when the effects of collisions are ignored. For this reason, the Vlasov equation is also called the collisionless Boltzmann equation. By ignoring the effects of collisions from the start, we can derive the Vlasov equation as follows.

Consider \( f_s(x,v,t) \) as a probability density associated with an ensemble of systems. This probability density can be thought of as a fluid in six-dimensional phase space. Since particles are neither created nor destroyed, this fluid must satisfy a continuity equation with the form

\[
\partial_t f_s(x,v,t) + \nabla_x \cdot \left( \frac{dx}{dt}_{\text{orbit}} f_s \right) + \nabla_v \cdot \left( \frac{dv}{dt}_{\text{orbit}} f_s \right) = 0
\]

(6.1)
where \( \frac{d}{dt} \big|_{\text{orbit}} \) refers to the orbit of the fluid element at the position \((x, v)\) in phase space. But the fluid represents the probability density of particles; therefore the orbit of the fluid element must be the same as the orbit of a particle of species \( s \) at position \( x \) with velocity \( v \). With this identification, we have immediately
\[
\frac{dx}{dt} \bigg|_{\text{orbit}} = v
\]  
(6.2)

and
\[
\frac{dv}{dt} \bigg|_{\text{orbit}} = \frac{q_s}{m_s} \left[ E(x, t) + \frac{v}{c} \times B(x, t) \right]
\]  
(6.3)

where because the effects of collisions are being ignored the fields \( E \) and \( B \) are the smooth, ensemble averaged fields satisfying Maxwell’s equations (3.28). Equation (6.1) becomes
\[
\partial_t f_s(x, v, t) + \nabla_x \cdot (v f_s) + \frac{q_s}{m_s} \nabla_v \cdot \left[ (E + \frac{v}{c} \times B) f_s \right] = 0
\]  
(6.4)

With the vector identity \( \nabla \cdot (ab) = b \nabla \cdot a + a \cdot \nabla b \), we find
\[
\partial_t f_s(x, v, t) + v \cdot \nabla_x f_s + \frac{q_s}{m_s} (E + \frac{v}{c} \times B) \cdot \nabla_v f_s = 0
\]  
(6.5)

which is the Vlasov equation [1].

**EXERCISE** Verify that the two terms dropped in going from (6.4) to (6.5) indeed vanish.

When this equation, one for each species, is combined with Maxwell’s equations (3.28), we have a complete description of the behavior of a plasma. Although in principle the Vlasov equation only applies to an ensemble of plasmas, in practice we assume that, because of the large number of particles in a single plasma, the fluctuations are so small that the Vlasov equation yields good predictions for a single plasma. Since collisions have been ignored, the Vlasov equation applies only when collisional effects are unimportant. Often, this means that we are limited to phenomena with a characteristic frequency \( \omega \gg \nu_e = \omega_e / \Lambda \).

### 6.2 Equilibrium Solutions

For time scales short compared to a collision time \( \nu_e^{-1} = \Lambda \omega_e^{-1} \), we are interested in finding steady-state solutions to the Vlasov equation (6.5), that is, those for which \( \partial_t f_s = 0 \). (In this chapter, the words “equilibrium” and “steady-state” are used synonymously.) Of course, there is no guarantee that such steady-state solutions are stable to small perturbations. (A pencil standing on its tip is a steady-state solution, but not a stable one.)

As we look for solutions to the Vlasov equation, it is useful to interpret the left side of (6.5) as the total time derivative of \( f_s \) along a particle orbit. Consider a
particle of species \( s \) whose orbit in six-dimensional phase space is \( X(t), V(t) \), where \( X(t) \) is the function that gives the position \( x \) in real space of the particle at time \( t \), and \( V(t) \) is the function that gives the position \( v \) in velocity space of the particle at time \( t \). Then the total time derivative of any quantity, measured along the test particle’s orbit in phase space, is

\[
\frac{D}{Dt} = \partial_t + \frac{dX(t)}{dt} \cdot \nabla_x + \frac{dV(t)}{dt} \cdot \nabla_v \\
= \partial_t + \frac{dx}{dt} \bigg|_{\text{orbit}} \cdot \nabla_x + \frac{dv}{dt} \bigg|_{\text{orbit}} \cdot \nabla_v \\
= \partial_t + v \cdot \nabla_x + \frac{q_s}{m_s} (E + \frac{v}{c} \times B) \cdot \nabla_v
\]  

(6.6)

where we have inserted (6.2) and (6.3). Thus, the Vlasov equation (6.5) simply says

\[
\frac{D}{Dt} f_s(x, v, t) = 0
\]

(6.7)

Knowledge of the form (6.7) gives us one way to solve the Vlasov equation (6.5). Suppose we construct \( f_s \) out of functions \( C_i(x, v, t) \) that are constants of the motion along the orbit of a particle. Then by (6.7),

\[
\frac{D}{Dt} f_s(C_i(x, v, t)) = \sum_i \frac{\partial f_s}{\partial C_i} \frac{D}{Dt} C_i = 0
\]

(6.8)

so that the Vlasov equation (6.5) is satisfied. Thus, any distribution that is a function only of the constants of the motion of the individual particle orbits is a solution of the Vlasov equation.

In the present section we are interested only in equilibrium solutions that do not depend explicitly on time. Noting that the fields \( E \) and \( B \) in (6.5) can be combinations of externally imposed fields and self-consistent fields, we consider the following cases.

**CASE A: E = B = 0**

In the absence of external fields, the energy \( \frac{1}{2} m_s v^2 \) and momentum \( m_s v = m_s(v_x, v_y, v_z) \) of a particle are constants of the motion. Thus, any function

\[
f_s = f_s(v_x, v_y, v_z)
\]

(6.9)

is a solution of the time-independent Vlasov equation. This can also be seen by writing the time-independent Vlasov equation with no external fields,

\[
v \cdot \nabla_x f_s = 0
\]

(6.10)

to which (6.9) is seen to be a solution.

**CASE B: E = 0, B = CONSTANT**

In the presence of a uniform background magnetic field, the total particle momentum is no longer a constant. If we choose the magnetic field in the \( \hat{z} \)-direction, then the constants of the motion are the momentum \( m_s v_z \) in the \( \hat{z} \)-direction and the energy \( \frac{1}{2} m_s v^2 \equiv \frac{1}{2} m_s (v_x^2 + v_y^2) \) in the plane perpendicular to the magnetic
field. Thus, any function

\[ f_s = f_s(v_x, v_z) \]  \hspace{1cm} (6.11)

is an equilibrium solution to the Vlasov equation in the presence of a uniform magnetic field.

**EXERCISE** Show (Chapter 1) that \( v_x \) is a constant of the motion in a uniform magnetic field. Verify by direct calculation that (6.11) is a solution of the Vlasov equation (6.5) in this case.

**CASE C: B = 0, E ≠ 0**

In the presence of an arbitrary electric field \( \mathbf{E}(x) = -\hat{x} \frac{d}{dx} \varphi(x) \) in the \( \hat{x} \)-direction, the particle constants of the motion are the momenta \( m_x v_x \) and \( m_z v_z \), and the energy \( \frac{1}{2} m_x v_x^2 + q_e \varphi(x) \) associated with motion in the \( \hat{x} \)-direction. Thus,

\[ f_s = f_s(v_x^2 + 2q_e \varphi(x)/m_z v_z, v_z) \]  \hspace{1cm} (6.12)

is an equilibrium distribution function. (Note that \( f_s \) can also depend upon the sign of \( v_x \).

**EXERCISE** Verify by direct substitution that (6.12) is a solution of the Vlasov equation (6.5) in this case.

In addition to these three simple cases, there are other important examples that are used. For example, in Chapter 2 we discussed the adiabatic invariants that are approximate constants of motion. Using these adiabatic invariants, one can construct approximate equilibrium distribution functions. Such solutions find wide applications in the study of magnetic confinement devices such as the tokamak and mirror machine.

### 6.3 ELECTROSTATIC WAVES

One of the simplest and most instructive predictions of Vlasov theory is the existence of electrostatic waves, waves that have only an electric field with no magnetic field, and in the small amplitude limit have a time and spatial dependence

\[ \sim \exp(i \mathbf{k} \cdot \mathbf{x} - i \omega t) + \text{c.c. (complex conjugate), where } \mathbf{k} \parallel \mathbf{E} \]

**EXERCISE** Show that for waves with \( \mathbf{k} \parallel \mathbf{E} \), Maxwell's equations predict no magnetic field.

We begin with the simple situation of a plasma with no applied electric or magnetic fields. Each species has a distribution function

\[ f_s = f_{s0} + f_{s1} \]  \hspace{1cm} (6.13)

where \( f_{s0} = f_{s0}(\mathbf{v}) \) is one of the equilibrium solutions discussed in the previous section, and \( f_{s1}(\mathbf{x}, \mathbf{v}, t) \) is a small perturbation associated with the small-amplitude wave. For each species,

\[ \int d\mathbf{v} \ f_{s0}(\mathbf{v}) = n_0 \]  \hspace{1cm} (6.14)
where \( n_0 \) is the average number of particles per unit configuration space. Choosing the electric field in the \( \hat{x} \)-direction, and treating waves with a spatial variation in the \( \hat{x} \)-direction only, the Vlasov equation is

\[
\partial_t f_s + v_x \partial_x f_s + \frac{q_s}{m_s} E \partial_{v_x} f_s = 0
\]  

(6.15)

With \( f_{s0} \) a zero order quantity, and \( f_{s1} \) and \( E \) small quantities of first order, we look for linearized solutions of (6.15). The zero order terms in (6.15) yield

\[
\partial_t f_{s0} + v_x \partial_x f_{s0} = 0
\]  

(6.16)

which is trivially satisfied by our equilibrium solutions \( f_{s0} = f_{s0}(v) \). The first order terms in (6.15) are

\[
\partial_t f_{s1} + v_x \partial_x f_{s1} + \frac{q_s}{m_s} E \partial_{v_x} f_{s0} = 0
\]  

(6.17)

Looking for plane wave solutions \( \sim \exp(i k_x - i \omega t) \) this is

\[
-i \omega f_{s1} + i k v_x f_{s1} = -\frac{q_s}{m_s} E \partial_{v_x} f_{s0}
\]  

(6.18)

or

\[
f_{s1}(x, v, t) = -\frac{iq_x/m_s}{\omega - k v_x} E \partial_{v_x} f_{s0}(v)
\]  

(6.19)

The only one of Maxwell’s equations (3.28) needed for electrostatic waves is Poisson’s equation, which in the present case is

\[
\begin{align*}
ike &= 4\pi e(n_i - n_e) \\
&= 4\pi e \int dv (f_i - f_e) \\
&= 4\pi e \int dv (f_{i1} - f_{e1}) \\
&= -i4\pi e^2 E \int dv \left[ \frac{m_i^{-1} \partial_{v_x} f_{s0}}{\omega - k v_x} + \frac{m_e^{-1} \partial_{v_x} f_{e0}}{\omega - k v_x} \right]
\end{align*}
\]  

(6.20)

Eliminating \( E \) from both sides we obtain the dispersion relation for electrostatic waves in an unmagnetized plasma,

\[
1 + \frac{\omega_p^2}{k^2} \int dv \frac{d_0 g(u)}{\omega / k - u} = 0
\]  

(6.21)

where

\[
g(v_x) = \frac{m_e}{n_0 m_i} \int dv_y dv_z f_{s0}(v) + \frac{1}{n_0} \int dv_y dv_z f_{e0}(v)
\]  

(6.22)

Notice that the ion component of \( g \) is reduced by the factor \( m_e / m_i \). For example, if the electrons and ions are Maxwellian, we have

\[
f_{s0} = \frac{n_0}{(2\pi)^{3/2} v_s^3} \exp \left[ -\left(v_{x0}^2 + v_{y0}^2 + v_{z0}^2 \right) / 2v_s^2 \right]
\]  

(6.23)

whereupon
\begin{align*}
g(v_i) &= \frac{1}{(2\pi)^{1/2}v_e} \exp(-v_i^2/2v_e^2) \\
&\quad + \frac{m_e}{m_i} \frac{1}{(2\pi)^{1/2}v_i} \exp(-v_i^2/2v_i^2) \\
&\text{where as usual } v_i^2 \equiv T_i/m_i.
\end{align*}

**EXERCISE** Verify that the Maxwellian (6.23) satisfies the normalization (6.14).

For equal temperatures \( T_e = T_i \), we have \( v_i \ll v_e \), and \( g(u) \) is as shown in Fig. 6.1. Notice that \( g(u) \) has the units (velocity\(^{-1}\)). The ion contribution appears tiny when compared to the electron contribution. However, for low frequency motions the ion contribution can be very important, as in the ion-acoustic wave.

Let us use the dispersion relation (6.21) to find the relation between frequency \( \omega \) and wave number \( k \) for high frequency electron plasma waves called *Langmuir waves*. The high frequency of these waves implies that the massive ions do not have time to respond to them, so we ignore the ion contribution to \( g(u) \) in (6.22), that is, we let \( m_i \to \infty \). This is equivalent to ignoring the ion motion in our derivation of the plasma frequency in Section 1.4. The dispersion relation (6.21) includes an integration over an integrand with a pole at \( u = \omega/k \). This pole must be handled with care. For the present, suppose we restrict ourselves to waves such that \( \omega/k \gg u \) for all \( u \) for which \( g(u) \) is appreciable, so that \( \partial_u g(u) = 0 \) at \( u = \omega/k \) (Fig. 6.2). With this assumption, (6.21) can be integrated by parts to obtain

\[ 1 - \frac{\omega^2}{k^2} \int_0^\infty du \frac{g(u)}{(\omega/k - u)^2} = 0 \quad (6.25) \]

where the boundary terms vanish because \( g(u \to \pm \infty) = 0 \). Expanding the denominator up to and including second order terms in \( uk/\omega \), we find

\[ 1 - \frac{\omega^2}{k^2} \int du g(u) \left( 1 + \frac{2uk}{\omega} + \frac{3u^2k^2}{\omega^2} \right) = 0 \quad (6.26) \]

**EXERCISE** Verify the expansion.

---

**Fig. 6.1** The function \( g(u) \) as predicted by (6.22) for an equal temperature Maxwellian plasma.
The Langmuir wave calculation of Section 6.3 is appropriate only when the phase speed \( \omega/k \) of the wave is much larger than the thermal speed \( v_c \).

With \( g(u) \) given by the first term on the right of (6.24), we have \( \int du \, g(u) = 1 \), \( \int du \, g(u)u = 0 \), \( \int du \, g(u)u^2 = v_c^2 \).

**EXERCISE** Verify these statements.

Equation 6.26 then predicts

\[ 1 - \frac{\omega_c^2}{\omega^2} - \frac{3k^2v_e^2\omega_c^2}{\omega^4} = 0 \quad (6.27) \]

which upon solving for \( \omega^2 \) and assuming \( k^2v_e^2 \ll \omega^2 \) yields

\[ \omega^2 = \omega_c^2 + 3k^2v_e^2 \quad (6.28) \]

which is the famous *Langmuir wave dispersion relation*; it can easily be committed to memory.

**EXERCISE**

(a) Obtain (6.28) from (6.27) with the given assumptions.

(b) Verify that (6.28) is consistent with the given assumptions.

(c) Show that (6.28) is equivalent to \( \omega = \omega_c(1 + 3k^2\lambda_c^2/2) \).

(d) Use the result of Problem 1.3 to modify (6.28) to include the effects of ion motion.

In the next section we shall return to the dispersion relation (6.21) and show how to properly treat the pole when we do not have \( d_u \, g(u) = 0 \) at \( u = \omega/k \).

### 6.4 Landau Contour

In this section, we present a more complete treatment of electrostatic waves, which includes a careful evaluation of the pole in the dispersion relation (6.21). As shown by Landau [2], the best way to proceed is by solving the Vlasov equation (6.17) and Poisson’s equation (6.20) in the context of an initial value problem.
To simplify the discussion, we treat only high frequency Langmuir waves and ignore ion motion. Looking for waves with the spatial dependence \( \sim \exp(ikx) \), and denoting the first order electron distribution by \( f_i(k,v,t) \), Eq. (6.17) becomes

\[
\partial_t f_i + ikv_x f_i - (e/m_e)E \partial_v f_{i0} = 0 \tag{6.29}
\]

When we use the Laplace transform convention (5.13) to (5.14), and the fact that the Laplace transform of \( d_i g(t) \) is \(-i\omega g(\omega) - g(t = 0)\), the Laplace transform of (6.29) is

\[
-i\omega f_i(k,v,\omega) + ikv_x f_i - (e/m_e)E(\omega)\partial_v f_{i0} = f_i(k,v,t = 0) \tag{6.30}
\]

**Exercise** Demonstrate that the Laplace transform of \( d_i g(t) \) is \(-i\omega g(\omega) - g(t = 0)\).

Poisson's equation (6.20) is in this case

\[
ike(\omega) = -4\pi e \int dv \, f_i(k,v,\omega) \tag{6.31}
\]

Solving (6.30) for \( f_i(k,v,\omega) \), we obtain

\[
f_i(k,v,\omega) = \frac{(e/m_e)E(\omega)\partial_v f_{i0} + f_i(k,v,t = 0)}{-i\omega + ikv_x} \tag{6.32}
\]

which when substituted in (6.31) yields

\[
ike \left[ 1 - \frac{4\pi e^2/m_e}{k^2} \int dv \, \frac{\partial_v f_{i0}}{v_x - (\omega/k)} \right] E(\omega) = \frac{-4\pi e}{ik} \int dv \, \frac{f_i(k,v,t = 0)}{v_x - (\omega/k)} \tag{6.33}
\]

The factor in brackets on the left is the dielectric function

\[
\epsilon(k,\omega) = 1 - \omega_s^2 \frac{1}{k^2} \int du \, \frac{du \, g(u)}{u - (\omega/k)} \tag{6.34}
\]

where the definition (6.22) of \( g(u) \) has been used. Note that \( \epsilon(-k,-\omega^*) = \epsilon^*(k,\omega) \). Equation (6.33) then becomes

\[
E(\omega) = \frac{4\pi e}{k^2\epsilon(k,\omega)} \int dv \, \frac{f_i(k,v,t = 0)}{v_x - (\omega/k)} \tag{6.35}
\]

As with all Laplace transforms, \( E(\omega) \) is defined only for \( \omega_i \) sufficiently large, and the inverse Laplace transform

\[
E(t) = \int_k \frac{d\omega}{2\pi} E(\omega)e^{-i\omega t} \tag{6.36}
\]

is carried out along the Laplace contour as shown in Fig. 6.3. The Laplace contour must pass above all poles of \( E(\omega) \), which by (6.35) includes all zeros of \( \epsilon(k,\omega) \). With the Laplace contour as shown in Fig. 6.3, we have \( \omega_i > 0 \) everywhere on the contour and thus \( \omega_i > 0 \) in the evaluation of \( \epsilon(k,\omega) \) in (6.34). By analytically continuing the function \( g(u) \) to the entire complex \( u = u_1 + iu_2 \)-plane, we can think of the integration in (6.34) as occurring along the real \( u \)-axis, with a pole at \( u = \omega/k \) in the upper half \( u \)-plane, as shown in Fig. 6.4.
The inverse Laplace transform (6.36) is accomplished by analytically continuing $E(\omega)$ to the entire complex $\omega$-plane. By (6.35), when we analytically continue $E(\omega)$, we must analytically continue $\epsilon(k, \omega)$. This means that when $\omega$ crosses the real $\omega$-axis from above to below, we cannot allow the pole in Fig. 6.4 to cross the integration contour; if it did, the value of $\epsilon(k, \omega)$ would jump by $-2\pi i$ times the residue at $u = \omega/k$. Thus, we must deform the integration contour in the complex $u$-plane as shown in Fig. 6.5 when $\omega_i < 0$. The two sets of contours shown in Figs. 6.4 and 6.5 are collectively known as the Landau contour. A similar contour must be used to evaluate the other integral in (6.35).

With $E(\omega)$ in (6.35) analytically continued to the entire complex $\omega$-plane, the $L$ contour in (6.36) can be deformed as shown in Fig. 6.6. We do not attempt to close the contour with a semicircle in the lower half $\omega$-plane, since it is not clear from

---

Fig. 6.3 Laplace contour.

Fig. 6.4 Contour of integration used in evaluating the dielectric function (6.34) when $\omega_i > 0$. 

(6.35) that $E(\omega)$ falls off fast enough at large negative $\omega_i$ for this to be done. Rather, we treat each part of the contour in Fig. 6.6 separately. There are four types of contributions. First, there are the poles of $E(\omega)$ such as the one at point $A$ in Fig. 6.6. We assume that this pole comes from a zero of $\epsilon(k, \omega)$ rather than from the other factor on the right of (6.35). Denoting the frequency at point $A$ by $\omega_A$, this pole contributes a term to $E(t)$ with the time dependence $\exp(-i\omega_A t)$. We call these contributions the normal modes, and we note that since the frequencies of the normal modes are given by $\epsilon(k, \omega) = 0$, they correspond to the waves found by solving the dispersion relation (6.21) in the previous section. After some time has

Fig. 6.5 Contour of integration used in evaluating the dielectric function (6.34) when $\omega_i < 0$.

Fig. 6.6 Deformed Laplace contour used in taking the inverse Laplace transform (6.36).
elapsed, the dominant contribution from the normal modes comes from the one with the largest imaginary part of the frequency, as in point \(A\) of Fig. 6.6. If this is positive, the normal mode is unstable and grows with time; if it is negative, the normal mode is damped and decays with time.

Second, there are contributions from segments like the one from point \(B\) to point \(C\). With the contour a distance \(\gamma > 0\) below the real \(\omega\)-axis, this contribution is of the form

\[
E(t) \sim \int_{\gamma}^{C} \frac{d\omega}{2\pi} E(\omega)e^{-i\omega t} = e^{-\gamma t} \int_{\gamma}^{C} \frac{d\omega}{2\pi} E(\omega)e^{-i\omega t}
\]

which decays very rapidly with time. Thus, after an initial transient period of time, these contributions can be ignored.

Third, there are contributions from the two segments like the one from point \(D\) to point \(E\), of the form

\[
E(t) \sim \int_{D}^{E} \frac{d\omega}{2\pi} E(\omega)e^{-i\omega t}
\]

\[
= e^{-i\omega_{0}t} \int_{D}^{E} \frac{d\omega}{2\pi} E(\omega_{0} + i\omega_{1})e^{i\omega_{1}t}
\]

These contributions can be ignored since \(E(\omega)\) is small for \(\omega_{0} \to \infty\); by (6.35) it varies as \(\omega^{-1}\) for large \(\omega\).

Fourth, the segment from point \(E\) to infinity gives a contribution

\[
E(t) \sim \int_{E}^{\infty} \frac{d\omega}{2\pi} e^{-i\omega t} E(\omega)
\]

which vanishes since for \(\omega_{0} \to \infty\) the integrand oscillates infinitely fast.

Thus, the response to an initial perturbation consists of normal modes that oscillate with the normal mode frequencies given by the dispersion relation (6.21), and transients. After some time, the normal mode with the largest imaginary part dominates. This discussion refers to a single wave number \(k\). A spatially localized perturbation in a plasma will have a spectrum of wave numbers, and the response after an initial transient period will consist of a spectrum of normal modes at different wave numbers. If any one of the normal mode frequencies has a positive imaginary part, the plasma is unstable and the perturbation grows with time. If all of the normal mode frequencies have negative imaginary parts, the perturbation eventually damps away. In the next section, we quantitatively evaluate the real and imaginary parts of the normal mode frequencies in terms of the zero-order distribution function \(f_{0}(v)\).

### 6.5 Landau Damping

In this section, we return to the Langmuir wave dispersion relation (6.21) and use our knowledge of the integration contours to carefully evaluate the contribution of the pole at \(u = \omega/k\). This calculation is especially elegant when we assume that \(|\omega_{1}| \ll |\omega_{0}|\), which can be checked after \(\omega\) is calculated.

Writing the dispersion relation (6.21) in the form
\[
\epsilon(k, \omega) = \epsilon_r + i \epsilon_i = 0 \tag{6.40}
\]
and Taylor expanding about \( \omega = \omega_i \), yields
\[
\epsilon(k, \omega) + i \epsilon_i(k, \omega) + i \omega_i \left. \frac{\partial \epsilon_i(k, \omega)}{\partial \omega} \right|_{\omega = \omega_i} = 0 \tag{6.41}
\]
Here the term \( \sim \omega_i \partial \epsilon_i / \partial \omega \) is ignored because it is the product of \( \omega_i \), which is small, and \( \partial \epsilon_i / \partial \omega \), which can be assumed to be small because \( \omega_i \sim \epsilon_i \), which can be seen by equating the real and imaginary parts of (6.41) separately to zero; this yields
\[
\epsilon_i(k, \omega_i) = 0 \tag{6.42}
\]
and
\[
\omega_i = -\left. \frac{\epsilon_i(k, \omega_i)}{\partial \epsilon_i(k, \omega) / \partial \omega} \right|_{\omega = \omega_i} \tag{6.43}
\]
When \( \omega_i = 0 \), the Landau contour is as shown in Fig. 6.7. The Plemelj formula (see Appendix C), as applied to the contour in Fig. 6.7, is
\[
\frac{1}{u - a} = P \left( \frac{1}{u - a} \right) + \pi i \delta(u - a) \tag{6.44}
\]
where \( P \) means principal value; this allows (6.34) to be written
\[
\epsilon(k, \omega_i) = 1 - \frac{\omega_i^2}{k^2} P \int_{-\infty}^{\infty} \frac{du}{u} \frac{d_x g(u)}{u - (\omega_i/k)} = -\pi i \frac{\omega_i^2}{k^2} \left. d_x g(u) \right|_{u = \omega_i/k} \tag{6.45}
\]
where for any function \( f(u) \),
\[
P \int_{-\infty}^{\infty} \frac{du}{u - a} f(u) = \lim_{\epsilon \to 0} \left[ \int_{-\infty}^{-\epsilon} du \frac{f(u)}{u - a} + \int_{\epsilon}^{\infty} du \frac{f(u)}{u - a} \right] \tag{6.46}
\]
The second term on the right of (6.44) comes from integrating around the semicircle in Fig. 6.7, which yields one-half of \( 2 \pi i \) times the residue. The integrand of (6.46) is shown as Fig. 6.8. The two large contributions of opposite sign cancel each other, so that the principal value is not very sensitive to the properties of the function \( f(u) \) near the pole at \( u = a \). From (6.42) and (6.45) we determine the real part of the frequency \( \omega_i \), from
\[
\epsilon_i(k, \omega_i) = 0 = 1 - \frac{\omega_i^2}{k^2} P \int_{-\infty}^{\infty} \frac{du}{u - (\omega_i/k)} \tag{6.47}
\]
For purposes of this integration, we can take \( d_x g(u) = 0 \) at \( u = \omega_i/k \), integrate by parts as in (6.25) to (6.27), and obtain
\[
\epsilon_i(k, \omega_i) = 1 - \frac{\omega_i^2}{\epsilon^2} - \frac{3k^2 \epsilon^2 \omega_i^2}{\omega_i^2} = 0 \tag{6.48}
\]
which by (6.28) yields, with the assumption \( k^2 \epsilon^2 << \omega_i^2 \),
\[
\omega_i^2 = \omega_c^2 + 3k^2 \epsilon^2 \tag{6.49}
\]
[Note that the expressions below (6.26) are valid for an arbitrary \( g(u) \), provided that \( \int du \ g(u)u = 0 \) and provided that one defines \( v_c \) by \( \int du \ g(u)u^2 = v_c^2 \).] In order to calculate \( \omega_i \) with (6.43) we need

\[
\frac{\partial \epsilon_i(k, \omega)}{\partial \omega} \bigg|_{\omega_i} = \frac{\partial \epsilon_r(k, \omega)}{\partial \omega_r} \approx \frac{2\omega_r^2}{\omega_r^3} \approx \frac{2}{\omega_c} \tag{6.50}
\]

where terms \( \mathcal{O}(k^2 \lambda_c^{-3}) \) have been ignored. Then by (6.43) and (6.45),

\[
\omega_i = \frac{\pi \omega_r^3}{2k^2} \left| d_u g(u) \right|_{u = \omega_r/k} \tag{6.51}
\]

The total normal mode frequency is finally

\[
\omega = \omega_r \left( 1 + \frac{3}{2} k^2 \lambda_c^{-2} \right) + i \frac{\pi \omega_r^3}{2k^2} \left| d_u g(u) \right|_{u = \omega_r/k} \tag{6.52}
\]

This equation is valid for all Langmuir waves such that \( k \lambda_c \ll 1 \). The generalization of (6.52) to encompass all wave numbers has been presented by Jackson [3].
When the slope of the distribution function $d_u g(u)|_{u=\omega/k}$ is negative, as with the Maxwellian distribution in Fig. 6.2, Langmuir waves have $\omega_l < 0$ and are Landau damped. When the slope is positive at $u = \omega_0/k$, as it is for a range of wave numbers in the “bump-on-tail” distribution in Fig. 5.1 at $t = 0$, then these wave numbers grow exponentially.

With a Maxwellian $g(u)$ given by the first term on the right of (6.24) one can explicitly evaluate $\omega_l$, which is

$$
\omega_l = \frac{\pi \omega_0^3}{2k^2} \frac{u}{(2\pi)^{1/2} v_e^3} \exp \left( -\frac{u^2}{2v_e^2} \right) \bigg|_{u=\omega_0/k}
= - \omega_e \left( \frac{\pi}{8} \right)^{1/2} \frac{1}{(k\lambda_e)^3} \exp \left( -\frac{3}{2} \right) \exp \left( -\frac{1}{2k^2 \lambda_e^2} \right)
$$

(6.53)

This vanishes for $k \to 0$ and increases rapidly with increasing wave number, such that for $k\lambda_e > 0.3$ the damping $\omega_l \sim \omega_e$ is so large that such waves are never observed.

In Section 6.7 we shall consider the physical mechanism of Landau damping. Heuristically, this can be considered as follows. Consider a wave with a phase speed $V_\varphi = \omega_0/k$ in a Maxwellian plasma (Fig. 6.2). Those particles with speeds $u$ very close to $V_\varphi$ interact strongly with the wave. Particles with speeds slightly faster than $V_\varphi$ are grabbed by the wave and slowed down, giving up energy to the wave, while particles with speeds slightly slower than the wave are sped up, taking energy from the wave. Since in a Maxwellian plasma there are more particles with speeds slightly less than $V_\varphi$ than with speeds slightly greater than $V_\varphi$, the net result is an energy gain by the particles and an energy loss by the wave; this is Landau damping.

On the other hand, consider a wave with phase speed $V_\varphi = \omega_0/k = u$ such that $d_u(g) > 0$ as on the left half of the “bump-on-tail” in Fig. 5.1. Now there are more particles slightly faster than $V_\varphi$ than slightly slower, the particles lose net energy to the wave, and the wave grows. These ideas will be made quantitative in Section 6.7.

### 6.6 WAVE ENERGY

In Section 6.5 the real and imaginary parts of the normal mode frequency for longitudinal waves are determined from a knowledge of the dielectric function $\epsilon(k, \omega)$. The importance of the dielectric function for longitudinal waves is due to its equivalence to Poisson’s equation

$$
i k E = 4 \pi \rho
$$

(6.54)

which is effectively replaced by

$$
i k \epsilon(k, \omega) E = 0
$$

(6.55)

for purposes of calculating normal modes [see (6.33)]. Thus, all of the physics contained in Poisson’s equation is also contained in the dielectric function. It is important to note that the “1” in the dielectric function

$$
\epsilon(k, \omega) = 1 - \frac{\omega_e^2}{k^2} \int \frac{d_u g(u)}{u - (\omega/k)}
$$

(6.34)
comes from the left side of Poisson’s equation (the “vacuum” contribution) whereas the other term comes from the right side of Poisson’s equation and represents the contribution of the plasma (plasma = medium = dielectric).

The dielectric function \(\epsilon(k,\omega)\) provides a very useful approach to wave energy. In this section, we present a somewhat heuristic demonstration of the relation between the dielectric function and wave energy. A more rigorous development can be found in Landau and Lifshitz [4].

When we deal with energy, we deal with squared quantities, such as electric fields; therefore we must be certain to have only real quantities before squaring. Consider a real oscillatory electric field

\[
\tilde{E}(t) = \frac{1}{2} E(t) \exp(-i\omega t) + \frac{1}{2} E^*(t) \exp(i\omega t)
\]

(6.56)

at a fixed spatial point. The time-averaged electric field energy density at this spatial point is

\[
W_E \equiv \frac{\tilde{E}^2}{8\pi} = \frac{1}{32\pi} \left[ E^2 \exp(-2i\omega t) + 2|E|^2 + E^*^2 \exp(2i\omega t) \right]
\]

\[
= \frac{|E|^2}{16\pi}
\]

(6.57)

where the terms at frequencies \(\pm 2i\omega t\) vanish on averaging over the fast time scale \(2\pi/\omega\).

With the real electric field \(\tilde{E}\) one can associate a real current \(\tilde{J}\), such that \(\tilde{J}(t) = \frac{1}{2} J(t) \exp(-i\omega t) + \frac{1}{2} J^*(t) \exp(i\omega t)\). Since we are dealing with linear waves, there is a linear relation between current and electric field,

\[
J(t) = \sigma(\omega) E(t)
\]

(6.58)

where \(\sigma(\omega)\) is the conductivity. There is a simple relationship between the conductivity \(\sigma(\omega)\) and the dielectric function \(\epsilon(\omega)\). Ampere’s law for longitudinal waves yields

\[
0 = \nabla \times B = \frac{4\pi}{c} J + \frac{1}{c} \frac{\partial E}{\partial t}
\]

\[
= \frac{-i\omega}{c} \left( 4\pi \sigma - i\omega \right) E
\]

\[
= \frac{1}{c} \frac{\partial D}{\partial t}
\]

\[
= \frac{-i\omega}{c} \epsilon(\omega) E
\]

(6.59)

with which we identify

\[
\epsilon(\omega) = 1 + \frac{4\pi i\sigma(\omega)}{\omega}
\]

(6.60)

where in accordance with electromagnetic theory we have introduced the displacement \(D = \epsilon E\).
Let us now develop an expression for the time rate of change of wave energy. From the first form of Ampere's law in (6.59), we obtain for real fields

\[ \frac{\partial E}{\partial t} = -4\pi J \]  

(6.61)

Multiplying each side by \( \frac{\dot{E}}{4\pi} \) yields

\[ \frac{1}{8\pi} \frac{d}{dt} (\dot{E})^2 = -\dot{E}J \]

\[ = -\frac{1}{4} [E \exp(-i\omega_t) + E^* \exp(i\omega_t)] [\sigma E \exp(-i\omega_t) + \sigma^* E^* \exp(i\omega_t)] \]  

(6.62)

where we have used (6.56) and (6.58). Taking the average of both sides over the short time \( 2\pi/\omega_r \), the second harmonic terms disappear and we have, using (6.57),

\[ \frac{1}{16\pi} \frac{d}{dt} |E|^2 = -\frac{1}{4} (E\sigma^* E^* + E^*\sigma E) \]

(6.63)

At this point we expand \( \sigma(\omega) \) exactly as we expanded \( \epsilon(\omega) \) in (6.41). From (6.60),

\[ \epsilon_r(\omega_r) = 1 - \frac{4\pi\sigma_r(\omega_r)}{\omega_r} \]

(6.64)

while

\[ \epsilon_i(\omega) = \frac{4\pi\sigma_i(\omega)}{\omega} \]

(6.65)

Consistent with the assumptions used in (6.41), we assume \( |\sigma_r(\omega_r)| \ll |\sigma_i(\omega)| \) and expand

\[ \sigma(\omega) = \sigma(\omega_r) + \frac{d\sigma}{d\omega} \bigg|_{\omega_r} i\omega + \ldots \]

\[ \equiv \sigma_r(\omega_r) + i\sigma_i(\omega) - \omega \frac{d\sigma}{d\omega} \bigg|_{\omega_r} \]

(6.66)

where we have ignored the term \( \omega_r (d\sigma_r/d\omega) \bigg|_{\omega_r} \) as being second order in small quantities. By (6.56), the normal mode electric field \( E(t) \) has the time dependence \( \exp(\omega t) \); therefore \( dE/dt = \omega E \), and we can write

\[ \omega \frac{d\sigma_i}{d\omega} \bigg|_{\omega_r} E = \frac{d\sigma_i}{d\omega} \bigg|_{\omega_r} \frac{d}{dt} E \]

(6.67)

whereupon (6.63) becomes

\[ \frac{1}{16\pi} \frac{d}{dt} |E|^2 = -\frac{1}{4} \left[ 2\sigma_r(\omega_r) |E|^2 - E \frac{d\sigma_i}{d\omega} \bigg|_{\omega_r} \frac{d}{dt} E^* \right. \]

\[ \left. - E^* \frac{d\sigma_i}{d\omega} \bigg|_{\omega_r} \frac{d}{dt} E \right] \]

\[ = -\frac{1}{2} \sigma_r(\omega_r) |E|^2 + \frac{1}{4} \frac{d\sigma_i}{d\omega} \bigg|_{\omega_r} \frac{d}{dt} |E|^2 \]

(6.68)

Moving a term to the left side, we find
\[
\frac{1}{16\pi} \frac{d}{dt} |E|^2 - \frac{1}{4} \frac{d\sigma_i}{d\omega} \left| \frac{d}{dt} |E|^2 = - \frac{1}{2} \sigma_i(\omega_i)|E|^2 \right. \tag{6.69}
\]

where we recognize the first term on the left as the time derivative of the electric field energy. Because the second term on the left involves \(\sigma_i\), we identify it as the time derivative of the particle energy contained in the current. The right side represents dissipation due to \(\sigma_i(\omega_i)\), which is proportional to \(\epsilon_i(\omega_i)\) and thus to \(\omega_i\) by (6.43). Since \(\sigma_i(\omega_i)\) represents dissipation, it is known as the resistive part of the conductivity, while \(\sigma_r(\omega_i)\) represents the particle energy in the wave and is thus called the reactive part of the conductivity.

The two terms on the left of (6.69) represent the time derivative of the total wave energy \(W_{\text{tot}}\). Thus, as a function of the electric field energy density (6.57),

\[
W_{\text{tot}} = \left(1 - 4\pi \left. \frac{d\sigma_i}{d\omega} \right|_{\omega_i} \right) W_E \tag{6.70}
\]

From (6.64), the constant can be written

\[
1 - 4\pi \left. \frac{d\sigma_i}{d\omega} \right|_{\omega_i} = \frac{d}{d\omega} [\omega \epsilon_i(\omega)]_{\omega_i} \tag{6.71}
\]

so the total wave energy is

\[
W_{\text{tot}} = \frac{d}{d\omega} [\omega \epsilon_i(\omega)]_{\omega_i} W_E \tag{6.72}
\]

For example, for Langmuir waves with \(k \lambda_s \rightarrow 0\), we have [see (6.48)]

\[
\epsilon_i(\omega) = 1 - \frac{\omega^2}{\omega_s^2} \tag{6.73}
\]

Therefore

\[
\frac{d}{d\omega} (\omega \epsilon_i) |_{\omega_i} = 1 + \frac{\omega^2}{\omega_s^2} |_{\omega_i} = 2 \tag{6.74}
\]

so there are equal amounts of energy in particles and electric field in a Langmuir wave.

**EXERCISE** Compare this result to your result in Problem 6.4.

Since the wave energy is \(\sim |E|^2\), and \(E \sim \exp(\omega t)\), we must have

\[
\frac{dW_{\text{tot}}}{dt} = 2\omega W_{\text{tot}} \tag{6.75}
\]

Let us verify that (6.75) is indeed satisfied by (6.69), which says

\[
\frac{dW_{\text{tot}}}{dt} = - \frac{1}{2} \sigma_i(\omega_i)|E|^2 = - \frac{1}{2} \sigma_i(\omega_i)16\pi W_E \]

\[
= - 8\pi \sigma_i(\omega_i) \left(\frac{1}{(d/d\omega)(\omega \epsilon_i)|_{\omega_i}}\right) W_{\text{tot}} \tag{6.76}
\]
But \((d/d\omega)(\omega \epsilon_r)|_{\omega_r} = \omega_r(d\epsilon_r/d\omega)|_{\omega_r}\) since \(\epsilon_r(\omega_r) = 0\) by (6.42), and \(\sigma_r(\omega_r) = \omega_r \epsilon_r(\omega_r)/4\pi\) from (6.65); thus (6.76) is

\[
\frac{dW_{\text{tot}}}{dt} = -\frac{2\epsilon_r(\omega_r)}{d\epsilon_r/d\omega|_{\omega_r}} W_{\text{tot}} = 2\omega_r W_{\text{tot}}
\]  

(6.77)

where (6.43) has been used to insert \(\omega_r\). Thus, (6.75) is indeed satisfied.

The convenient formulas (6.43) for growth rate and (6.72) for wave energy in terms of the dielectric function \(\epsilon(k, \omega)\) are applicable to all electrostatic waves in a plasma, and are very useful in practice. Because of the form (6.34), one can plausibly state that a full knowledge of \(\epsilon(k, \omega)\) for all values of \(k\) and \(\omega\) implies a full knowledge of the distribution function \(g(u)\). In the next section, we consider in detail the effect of an electrostatic wave on the distribution function; this leads to a microscopic understanding of Landau damping.

### 6.7 PHYSICS OF LANDAU DAMPING

In Section 6.5 the phenomenon of Landau damping (6.52) is introduced as a mathematical consequence of the solution of the dispersion relation. In the present section we discuss the detailed physics of Landau damping [5]. This is done by considering the effect of the small wave, associated with the perturbed distribution function \(f_1(x, v, t = 0)\), on the background plasma represented by \(f_0(v)\). For convenience in this section, we denote the \(x\)-component of velocity by \(v\), and suppress the “electron” subscript on \(f_1\) and \(f_0\).

Consider a linear Langmuir wave of the form \(E_i(x', t) = E_0 \sin (kx' - \omega_i t)\) where \(x'\) denotes the laboratory frame of reference, \(E_0\) is a small constant, and for the moment we ignore the imaginary part of the frequency. In the frame of reference \(x\) moving with the phase speed \(\omega_i/k > 0\) with respect to the laboratory frame, the wave field is independent of time and is given by \(E_i(x) = E_0 \sin (kx)\), as shown in Fig. 6.9. All of the particles in the background distribution function \(f_0(v)\) are affected by this electric field, and some are speeded up while others are slowed down. We focus our attention on only those particles in \(f_0(v)\) that have speed \(v_0\) in the lab frame at \(t = 0\) and, thus, have speed \(\tilde{v} = v_0 - v_i\) in the frame moving with the wave phase speed \(v_i = \omega_i/k\) (Fig. 6.10). This “beam” of particles with speed \(v_0\) in the lab frame and speed \(\tilde{v}_0\) in the wave frame will see the energy of some
Vlasov Equation

Fig. 6.10 Beam of electrons, all with speed $v_0$ with respect to the laboratory frame and speed $\bar{v}_0 = v_0 - v_e$ with respect to the moving frame.

...of its members increase with time and the energy of some of its members decrease with time, depending on the initial particle position $x_0$. After a time $t$, a particle will have experienced a change in speed $\Delta v$ (independent of frame) so that the particle's energy, as measured in the lab frame, suffers a change

$$\Delta E = \frac{1}{2} m_e (v_0 + \Delta v)^2 - \frac{1}{2} m_e v_0^2$$
$$= m_e v_0 \Delta v + \mathcal{O}[(\Delta v)^2]$$

(6.78)

where we shall ignore the term in $(\Delta v)^2$ in what follows; it can be shown that in the present derivation this term gives a negligible contribution to quantities of interest. We are interested in the average change in energy over a wavelength,

$$\langle \Delta E \rangle_{x_0} = m_e v_0 \langle \Delta v \rangle_{x_0}$$

(6.79)

Since $\Delta v$ can be calculated in any frame, we work in the wave frame. Then

$$\Delta v(t) = \int_0^t \dot{v}(t') dt' = -\frac{eE_0}{m_e} \int_0^t dt' \sin k\tilde{x}(t')$$

(6.80)

where $\tilde{x}(t)$ is the orbit of the particle. If we insert in (6.80) the unperturbed particle orbit $\tilde{x}(t) = x_0 + \bar{v}_0 t$, without the effects of the wave field, we would find $\langle \Delta v \rangle_{x_0} = 0$. Thus, we must include the lowest order correction to the particle orbit due to the effect of the wave. This is done as follows:

$$\Delta v(t) = -\frac{eE_0}{m_e} \int_0^t dt' \sin k\tilde{x}(t')$$
$$x_0 + \int_0^t dt'' \bar{v}(t'')$$
$$\bar{v}_0 = -\frac{eE_0}{m_e} \int_0^t dt''' \sin k\tilde{x}(t''')$$

(6.81)

where we have gone far enough to pick up the lowest order correction in $E_0$. Performing the last integration we find
\[ \tilde{v}(t') = \tilde{v}_0 + \frac{eE_0}{m_ek\tilde{v}_0} [\cos (kx_0 + k\tilde{v}_0 t') - \cos kx_0] \] (6.82)

The next to last integration yields

\[ \tilde{x}(t') = x_0 + \tilde{v}_0 t' - \frac{t'eE_0}{m_ek\tilde{v}_0} \cos (kx_0) \]
\[ + \frac{eE_0}{m_ek^2\tilde{v}_0^2} [\sin (kx_0 + k\tilde{v}_0 t') - \sin (kx_0)] \] (6.83)

The first integrand is of the form \( \sin (kx_0 + k\tilde{v}_0 t' + \tilde{\Delta}) \) where \( \tilde{\Delta} \) is proportional to \( E_0 \).

\[ \tilde{\Delta} = - \frac{t'eE_0}{m_\epsilon\tilde{v}_0} \cos (kx_0) \]
\[ + \frac{eE_0}{m_ek^2\tilde{v}_0^2} [\sin (kx_0 + k\tilde{v}_0 t') - \sin (kx_0)] \] (6.84)

Since we are looking for the lowest order correction in \( E_0 \), we can Taylor expand

\[ \sin (a + \tilde{\Delta}) = \sin a + \tilde{\Delta} \cos a \] (6.85)

to lowest order in \( \tilde{\Delta} \). Then

\[ \Delta v(t) = - \frac{eE_0}{m_\epsilon} \int_0^t dt' [\tilde{\Delta} \cos (kx_0 + k\tilde{v}_0 t') + \sin (kx_0 + k\tilde{v}_0 t')] \] (6.86)

We next wish to average \( \Delta v \) over one wavelength, upon which the \( \sin \) term disappears. The other terms are evaluated using the identities

\[ \langle \sin (u - a) \cos (u - b) \rangle_a = - \frac{1}{2} \sin (a - b) \] (6.87)
\[ \langle \sin (u - a) \sin (u - b) \rangle_a = \langle \cos (u - a) \cos (u - b) \rangle_a \]
\[ = \frac{1}{2} \cos (a - b) \] (6.88)

where \( \langle \rangle_a \) means an average over one period of the variable \( u \). We find

\[ \langle \Delta v(t) \rangle_{x_0} = \left( \frac{eE_0}{m_\epsilon} \right)^2 \frac{k}{2} \int_0^t dt' \left\{ - \frac{1}{k^2\tilde{v}_0^2} \sin (k\tilde{v}_0 t') \right\} \]
\[ + \frac{t'}{k\tilde{v}_0} \cos (k\tilde{v}_0 t') \] (6.89)

The integration can be performed, and yields

\[ \langle \Delta v(t) \rangle_{x_0} = \left( \frac{eE_0}{m_\epsilon} \right)^2 \frac{1}{2k^2\tilde{v}_0^2} \left[ 2[\cos (k\tilde{v}_0 t) - 1] \right] \]
\[ + k\tilde{v}_0 t \sin (k\tilde{v}_0 t) \] (6.90)

Our aim is to form the change of energy, \( \langle \Delta E \rangle_{x_0} = m_\epsilon v_0 \langle \Delta v \rangle_{x_0} \) and integrate over all velocities \( v_0 \) in the lab frame to find the total change in energy of the particles. Before doing so, let us evaluate (6.90) at early time, such that \( k\tilde{v}_0 t \ll 1 \). Note that early time for one "beam" of velocity \( \tilde{v}_0 \), may not be early time for another
"beam" of velocity $\gg \bar{v}_0$. Using the formulas

$$\sin x \approx x - \frac{x^3}{6} + \ldots \quad (6.91)$$

and

$$\cos x \approx 1 - \frac{x^2}{2} + \frac{x^4}{24} + \ldots \quad (6.92)$$

we find

$$2(\cos x - 1) + x \sin x \approx -\frac{x^4}{12} \quad (6.93)$$

Therefore (6.90) becomes

$$\langle \Delta v(t) \rangle_{\infty} = -\left(\frac{eE_0}{m_c}\right)^2 \frac{k^2 \bar{v}_0}{24} t^4 \quad k\bar{v}_0 t \ll 1 \quad (6.94)$$

Thus, we see that "beams" with $\bar{v} > 0$, that is, those moving faster than the wave, are indeed slowed down at early times, in the sense of an average over $x_0$. "Beams" with $\bar{v} < 0$, those moving slower than the wave, are sped up in an average sense.

We are now ready to integrate the spatially averaged energy change over all velocities, in the lab frame. We cannot use (6.94) for $\langle \Delta v \rangle_{\infty}$, because $k\bar{v}_0 t \ll 1$ is not true for all "beams" at a given time $t$. Rather, we use (6.90) to find the total energy change $W(t)$,

$$W(t) \equiv \int_{-\infty}^{\infty} d\tilde{v}_0 \int_{-\infty}^{\infty} f_0(\tilde{v}_0) \langle \Delta E \rangle_{\infty} = \int_{-\infty}^{\infty} d\tilde{v}_0 \int_{-\infty}^{\infty} f_0(\tilde{v}_0) \rho_{\infty} \langle \Delta v \rangle_{\infty} \quad (6.95)$$

where we have used (6.78). Since (6.90) involves velocities $\tilde{v}_0$ in the wave frame, it is convenient to make the change of variable $\tilde{v}_0 = v_0 - \psi$, in (6.95), which becomes

$$W(t) = \rho_{\infty} \int_{-\infty}^{\infty} d\tilde{v}_0 \tilde{f}(\tilde{v}_0)(\tilde{v}_0 + \psi)(\Delta v)_{\infty} \quad (6.96)$$

where $\tilde{f}(\tilde{v}_0) = f_0(\tilde{v}_0 + \psi)$. We expect the major contribution to (6.96) to come from particles with velocities close to $\tilde{v}_0 \approx 0$; this can be seen from the fact that the expression (6.90) for $\langle \Delta v \rangle_{\infty}$ varies as $(\tilde{v}_0)^{-1}$. We therefore expand $\tilde{f}(\tilde{v}_0) \approx \tilde{f}(0) + \tilde{v}_0 \tilde{f}'(0)$. The product

$$\tilde{f}(\tilde{v}_0)(\tilde{v}_0 + \psi) = \tilde{f}(0)\tilde{v}_0 + \tilde{f}(0)\psi$$

$$+ \tilde{v}_0 \tilde{f}'(0) + \tilde{v}_0 \psi \tilde{f}'(0) \quad (6.97)$$

has four terms. Since $\langle \Delta v \rangle_{\infty}$ in (6.90) is odd in $\tilde{v}_0$, the two terms in (6.97) that are even in $\tilde{v}_0$ will give zero when the integration in (6.96) is performed. Only the two odd terms in (6.97), $\tilde{f}(0)\tilde{v}_0$, and $\tilde{v}_0 \psi \tilde{f}'(0)$ contribute. Usually, the latter term makes a much larger contribution.

**EXERCISE** Verify this statement for a Maxwellian, with $\psi \gg \psi_c$. 
If we keep only the latter term, (6.96) becomes

$$W(t) = \frac{m_e v_e \tilde{f}^*(0)}{2k^2} \left( \frac{eE_0}{m_e} \right)^2 \int_{-\infty}^{\infty} \frac{d\tilde{v}_0}{\tilde{v}_0^2} \left[ 2[\cos(kt\tilde{v}_0) - 1] \right]$$

$$+ \ k\tilde{v}_0 t \sin(kt\tilde{v}_0) \right]$$

(6.98)

With the change of variable $x = k\tilde{v}_0 t$, the integral $I$ in (6.98) becomes

$$I = kt \int_{-\infty}^{\infty} \frac{dx}{x^2} \left[ 2(\cos x - 1) + x \sin x \right]$$

(6.99)

The second term is found from an integral table to yield

$$\int_{-\infty}^{\infty} \frac{dx}{x} \frac{\sin x}{x} = \pi$$

(6.100)

while the other term yields $-2\pi$.

**EXERCISE**

(a) Verify the last statement by changing the limits of integration to $(0, \infty)$, carefully integrating by parts, and using (6.100).

(b) Evaluate (6.100) using contour integration. First, move the contour off of the (nonexistent) pole at $z = 0$ and then expand the sine in terms of exponentials.

Thus, we find

$$W(t) = -\frac{\pi}{2} \frac{m_e v_e}{k} \tilde{f}^*(0) \left( \frac{eE_0}{m_e} \right)^2 t$$

(6.101)

or

$$W(t) = -\frac{\pi}{2} \frac{m_e \omega_r}{k^2} f_0'(v_e) \left( \frac{eE_0}{m_e} \right)^2 t$$

(6.102)

or identifying $f_0$ with $n_0 g$, and taking $\omega_r \approx \omega_e$,

$$W(t) = -\frac{\omega_e^3}{8k^2} g'(v_e) E_0^2 t$$

(6.103)

Equation 6.103 shows that the total particle energy is changing as the first power of time $t$, and is positive when $g'(v_e) < 0$ and negative when $g'(v_e) > 0$. The energy gained or lost by the particles must come from the wave. The rate of change of wave energy $W_{\text{wave}}$ must be equal and opposite to the rate of change of particle energy. From (6.103),

$$\frac{d}{dt} W_{\text{wave}} = -\frac{d}{dt} W(t) = \frac{\omega_e^3}{8k^2} g'(v_e) E_0^2$$

(6.104)

The total wave energy, averaged over a wavelength, is $W_{\text{wave}} = 2E_0^2 \langle \sin^2 (kx) \rangle / 8\pi = E_0^2 / 8\pi$, where the factor of 2 is introduced because a Langmuir wave has equal amounts of energy in electric field energy and in particle kinetic energy. Thus, (6.104) is

$$\frac{d}{dt} W_{\text{wave}} = \frac{\pi \omega_e}{k^2} g'(v_e) W_{\text{wave}}$$

(6.105)
If the electric field amplitude is varying with time as \( E_0(t) \sim \exp(\gamma t) \), then the wave energy \( W_{\text{wave}} \sim \exp(2\gamma t) \); thus
\[
\frac{dW_{\text{wave}}}{dt} = 2\gamma W_{\text{wave}}
\]  
(6.106)

Comparing (6.106) and (6.105), we find
\[
\gamma = \frac{\pi}{2} \frac{\omega_{\text{pe}}^2}{k^2} g'\left(v_{\text{pe}}\right)
\]  
(6.107)

which is in exact agreement with the formula (6.52) obtained by contour integration of the linearized Vlasov equation.

We see therefore that Landau damping is related to the initial behavior of the background particles, with particles moving slightly faster than the wave being slowed at early times and particles moving slightly more slowly than the wave being sped up at early times; this is true only in a spatially averaged sense. The net Landau damping (or Landau growth) comes from contributions from all particles, averaged over space; however, because of the \( v_{\text{pe}}^{-1} \) dependence in (6.90), particles close to the wave phase speed give the biggest contribution, which is why \( g'(v_{\text{pe}}) \) is so important.

The theory just developed is a linear one and thus is exact only for waves of infinitesimal amplitude. In the next section we discuss heuristically the modification of these ideas for waves of finite amplitude.

6.8 NONLINEAR STAGE OF LANDAU DAMPING

In previous sections we have treated linear Landau damping, first by integrating the linearized Vlasov equation, and then by considering the detailed orbits of the background distribution function. Let us next look at the consequences of finite wave amplitude.

We again think in terms of the initial value problem. We consider the background distribution function, in the presence of the wave \( \hat{E}(\hat{x},t) = E_0(t) \sin(k\hat{x} - \omega t) \). In the wave frame, moving at velocity \( v_{\phi} = \omega_0/k \) with respect to the lab frame, the electric field is \( E(x) = E_0 \sin kx \), with corresponding electrostatic potential \( \phi(x) = (E_0/k) \cos kx \) (Fig. 6.11). In this wave frame, ignoring the slow time dependence of \( E_0(t) \), the electrons see a time-independent electric field, so their total energy \( H = -e\phi(x) + \frac{1}{2}mv^2 \) is a constant, when \( v \) is measured in the wave frame. For each particle, the constant \( H \) is determined by the initial position and initial velocity; therefore,
\[
H = -e\phi[x(t)] + \frac{1}{2}mv^2(t) = -e\phi[x(t = 0)] + \frac{1}{2}mv^2(t = 0)
\]  
(6.108)

The corresponding equation of motion is
\[
m\ddot{x} = -eE_0 \sin kx = -eE_0 \frac{d}{dx} (-\cos kx)
\]  
(6.109)

Thus, the particles are moving in a potential well \(-e\phi(x) = -(eE_0/k) \cos kx\).
Consider all particles with $v = 0$ at time $t = 0$. These particles have different energies depending on their position; from (6.108),

$$H = -E_0[x(t = 0)]$$  \hspace{1cm} (6.110)

At $t = 0$, these particles find themselves in a potential field as shown in Fig. 6.12. Particles at $A$ do not move. Particles at $B$ begin to move in the well, with constant energy. Those at $C$ do the same. Those at $D$ are marginally stable; a slight perturbation will allow them to begin moving in the well. Each of these particles oscillates in the well with a certain frequency of oscillation, which decreases as we move up the well, until the frequency at $D$ is zero and the period infinite. Near the bottom of the well, at $B$ for instance, we can find the frequency of oscillation by expanding the force about $x = 0$; thus from (6.109),

$$m\ddot{x} = -eE_0 \sin kx \approx -eE_0 kx$$  \hspace{1cm} (6.111)

from which we identify the characteristic frequency of oscillation,

$$\omega_b^2 = \frac{eE_0 k}{m}$$  \hspace{1cm} (6.112)

or

$$\omega_b = \left(\frac{eE_0 k}{m}\right)^{1/2}$$  \hspace{1cm} (6.113)

where $\omega_b$ is known as the bounce frequency.
Linear Landau damping was derived on the basis of only small perturbations in particle orbits. However, after one-half of a bounce period, the particle at $B$ has moved a substantial fraction of a wavelength, and linear theory is invalidated. Thus, we expect linear Landau damping to hold only for short times, such that

$$t \ll \omega_b^{-1} = \left(\frac{m}{\varepsilon E_0 k}\right)^{1/2}$$  \hspace{1cm} (6.114)

Another way to look at this phenomenon is to draw the particle orbits in the $v$-$x$ plane, as shown in Fig. 6.13. The labels $A$, $B$, $C$, and $D$ in this figure correspond to the previous figure, all for particles with initial velocity $v = 0$. The solid lines indicate the orbits of these particles, and also indicate curves of constant energy. Consider the particle at $E$ at the initial time $t = 0$. It has the same position as the particle at $B$ and, thus, the same potential energy. However, because it also has a finite kinetic energy at $t = 0$, its total energy $-e\varphi_x + \frac{1}{2}mv^2$ is larger, and it finds itself on the same orbit as particle $C$. For an even larger initial velocity, we find a particle at position $F$. This particle is called untrapped, since its orbit carries it out of the original wavelength and into the neighboring wavelength to the right. By contrast, the particles at $A$, $B$, $C$, and $E$ are called trapped, because their orbits remain forever in the original wavelength. The particle at $D$ is neither trapped nor untrapped; its orbit is called the separatrix because it separates the trapped orbits from the untrapped orbits.

At the initial time $t = 0$, the particles take off along their orbits, moving to the right if $v > 0$ and to the left if $v < 0$, as shown in Fig. 6.14. During the time each particle represented by a dot moves from its dot to the tip of its arrow, we have the period of linear Landau damping, or growth. When the slope of the distribution function is negative, this early time behavior results in Landau damping, with the particles on the average gaining energy from the wave; both trapped and untrapped particles contribute. However, after a substantial fraction of a bounce period, the trapped particles are smeared out around their phase space orbits and the stage of linear Landau damping is over. The smearing process is facilitated by

![Fig. 6.13 Particle orbits in the $v$-$x$ plane, neglecting the self-consistent change in the wave electric field due to the motion of the particles.](image)
the fact that neighboring trapped particle orbits have slightly different bounce periods. At \( x = 0 \) in the wave frame, the initial distribution might be a Maxwellian, as in Fig. 6.15. At a much later time after many bounce periods, the particles with velocity \( v \approx v_\varphi \) are smeared out, and the distribution looks as in Fig. 6.16. The flat region is \( v_\varphi - v_i < v < v_\varphi + v_i \), where the *trapping speed* \( v_i \) is defined by

\[
\frac{1}{2} m v_i^2 = 2|\psi|_{\text{max}}
\]

or

\[
v_i = 2 \left( \frac{e}{m} \right)^{1/2} |\psi|_{\text{max}}^{1/2}
\]

or

\[
v_i = 2 \left( \frac{e E_{\text{tot}}}{mk} \right)^{1/2}
\]

Note the relation between the bounce frequency \( \omega_b \) from (6.113), and the trapping speed \( v_i \) from (6.117),

\[
\omega_b = \frac{1}{2} k v_i
\]

Fig. 6.15 Maxwellian at \( t = 0, x = 0 \).
Vlasov Equation

Fig. 6.16 Distribution at $x = 0$, $t \gg 0$.

We can now attempt to construct an overall scenario for the initial value problem of a finite amplitude Langmuir wave. At early time $t \ll \omega_p^{-1}$, we have Landau damping at the appropriate damping rate. At $t = \pi/\omega_p$, the trapped particles have gone through a half a bounce and as they start to come through the second half of a bounce, they can put back into the wave some of the energy that they initially took out of it. This reversal of energy is by no means complete, however, because by this time the trapped particles are out of phase with each other. We can then construct a picture of the behavior of wave amplitude versus time as shown in Fig. 6.17. Here, $\gamma_L$ is the Landau damping rate, and we have assumed $\gamma_L >> \omega_p$. For very large time, far off the right side of the figure, the curve will approach a straight line, all the phases will be completely mixed, and the wave will become a BGK mode [6] (see Section 6.13). Much of the present discussion has been heuristic. A completely self-consistent and nonlinear treatment of Langmuir waves is a very interesting current topic of research; see, for example, References [7] to [9].

Fig. 6.17 Langmuir wave amplitude versus time.
6.9 STABILITY: NYQUIST METHOD, PENROSE CRITERION

In Section 6.2 we discussed methods of constructing Vlasov equilibria. Once we have found these equilibria, we must ask the question: Are they stable or unstable? For example, we know that when the ions and electrons are both Maxwellian with no relative drift, we expect the system to be stable. On the other hand, when the electrons form a cold beam moving through cold ions, elementary fluid theory (see Chapter 7) predicts instability. The question of whether or not a spatially uniform equilibrium is stable can be answered by the Nyquist method. [Note that the equilibrium must be uniform; this means that the Nyquist method unfortunately cannot determine the stability of BGK modes (see Section 6.13)].

We know that all information concerning the linear stability of an equilibrium to electrostatic perturbations is contained in the dielectric function $\epsilon(k, \omega)$, which is obtained by linearizing the basic physical equations about an equilibrium. Knowledge of $\epsilon(k, \omega)$ everywhere in the complex $\omega$-plane determines all of the electrostatic stability properties of a system.

Consider a general function $\epsilon(k, \omega)$. Regarding $k$ as a fixed real positive constant, we can then consider $\epsilon$ to be a function of $\omega$ only. Form a new function $(1/\epsilon) \partial \epsilon / \partial \omega$. Then it turns out that

$$\frac{1}{2\pi i} \int_{c_{\omega}} \frac{1}{\epsilon} \frac{\partial \epsilon}{\partial \omega} d\omega = N = \# \text{ of zeros of } \epsilon(k, \omega) \text{ inside the contour} \quad (6.119)$$

where $c_{\omega}$ is any closed contour in the complex $\omega$-plane, the integration is in the counterclockwise direction, and we assume $\partial \epsilon / \partial \omega$ has no poles in the enclosed region, and $\epsilon$ has only simple zeros. The derivation of (6.119) is as follows: Near any simple zero $\omega_0$ of $\epsilon$, we have

$$\epsilon(k, \omega) = 0 + \left. \frac{\partial \epsilon}{\partial \omega} \right|_{\omega_0} (\omega - \omega_0) + \ldots \quad (6.120)$$

while

$$\frac{\partial \epsilon}{\partial \omega} = \left. \frac{\partial \epsilon}{\partial \omega} \right|_{\omega_0} + \left. \frac{\partial^2 \epsilon}{\partial \omega^2} \right|_{\omega_0} (\omega - \omega_0) + \ldots \quad (6.121)$$

Thus, near $\omega_0$, we have

$$\frac{1}{\epsilon} \frac{\partial \epsilon}{\partial \omega} = \frac{1}{\omega - \omega_0} \quad (6.122)$$

A trivial application of the residue theorem to the left side of (6.119) then yields the right side of (6.119). Thus, (6.119) tells us the number of roots of $\epsilon(\omega, k) = 0$ in a certain region of $\omega$-space. In order to locate all the unstable roots, we simply need to evaluate (6.119) along a contour that includes all of the upper half $\omega$-plane, since having $\epsilon(k, \omega) = 0$ when $\omega_i > 0$ means instability. In Fig. 6.18, (6.119) would yield $N = 2$, while in Fig. 6.19, (6.119) would yield $N = 0$ (left), $N = 1$ (middle), and $N = 3$ (right).

As one integrates around a contour in the $\omega$-plane, it is possible to draw a corresponding contour in the complex $\epsilon$-plane. In that plane we have from (6.119)

$$\frac{1}{2\pi i} \int_{c_{\omega}} \frac{1}{\epsilon} \frac{\partial \epsilon}{\partial \omega} d\omega = \frac{1}{2\pi i} \int_{c_{\epsilon}} \frac{1}{\epsilon} d\epsilon = N \quad (6.123)$$
where $c_\epsilon$ is the contour in the $\epsilon$-plane obtained by evaluating $\epsilon(k, \omega)$ at each point on the contour $c_\omega$ in the $\omega$-plane. Thus, the middle term in (6.123) says that the contour $c_\epsilon$ must pick up $N$ zeros of $\epsilon$, so that in the $\epsilon$-plane it must circle the origin $N$ times. Three examples are shown in Fig. 6.19.

We thus have a powerful technique, the Nyquist method, for determining whether a physical system described by a dielectric function $\epsilon(k, \omega)$ is stable or not. We simply draw the curve $c_\epsilon$ in the $\epsilon$-plane, found by mapping the curve $c_\omega$, which encircles the upper half $\omega$-plane. If $c_\epsilon$ does not encircle the origin $\epsilon = 0$, then the system is stable. If $c_\epsilon$ does encircle the origin one or more times, the system is unstable. The Nyquist method by itself does not tell us the growth rate of the instability.

Fig. 6.19 Three examples of contours $c_\omega$ and the corresponding contours $c_\epsilon$. 
Let us test these ideas using the Vlasov–Poisson system, as represented by \( \epsilon(k, \omega) \) in (6.34) for any \( \omega_i \), and in (6.45) for \( \omega_i = 0 \). We are trying to map the \( c_\omega \) contour onto the \( \epsilon \)-plane. First, consider the semicircle at \( \infty \). Then (6.34) yields
\[
\epsilon(k, \omega) = 1 \quad (6.124)
\]
everywhere on the semicircle, since for \( |\omega| \to \infty \) the second term in (6.34) vanishes. The remainder of the \( c_\omega \) contour is the path from \( \omega = -\infty \) to \( \omega = +\infty \) along the real \( \omega \)-axis. But this is precisely the situation when we can use the form (6.45).

By looking at the sign of the imaginary term in (6.45), we can see that as \( \omega \to +\infty \), \( \epsilon_i > 0 \), while as \( \omega \to -\infty \), \( \epsilon_i < 0 \). Also, for large \( |\omega| \), \( \epsilon_i = 1 - \omega_i^2/\omega^2 \). We thus have the beginning of our path \( c_\epsilon \) in the \( \epsilon \)-plane as shown in Fig. 6.20. If the remaining part of the path \( c_\epsilon \) looks as it does in Fig. 6.21, we shall have no instability because the origin is not encircled. However, if the remainder of \( c_\epsilon \) looks as in Fig. 6.22 we have one unstable mode, because the origin is encircled once in the counterclockwise direction. Note that it is impossible to obtain the contour shown in Fig. 6.23 because this encircles the origin in the clockwise sense, predicting \( N = -1 \) by (6.123), which is nonsense.

Because of the handy formula (6.45), which describes the entire path \( c_\epsilon \) except for the point \( \epsilon = 1 \), we know immediately all the places where \( c_\epsilon \) crosses the real \( \epsilon \)-axis. These are just the places where \( \epsilon_i = 0 \), or by (6.45), where \( d_{\omega}g(u)|_{\omega/k} = 0 \). Thus, a single humped \( g(u) \) has only one position \( u_0 \) where \( d_{\omega}g(u) = 0 \). In this case, \( c_\epsilon \) can only cross the real \( \epsilon \)-axis in one place, and we immediately know that this is a stable system. This is because it is not possible, with what we already know about the contour \( c_\epsilon \), to encircle the origin in a counterclockwise sense and only cross the real \( \epsilon \)-axis once.

![Fig. 6.20](image)

**Fig. 6.20** Portion of the contour \( c_\epsilon \) that comes from all portions of the \( c_\omega \) contour in Fig. 6.18 with \( |\omega| \to \infty \).
Fig. 6.21 A contour $c_\epsilon$ that would yield no instability.

We can verify this conclusion by evaluating $\epsilon_\tau$ at the position $\omega = ku_0$ where $\epsilon_i$ vanishes. From (6.45),

$$
\epsilon_\tau = 1 - \frac{\omega^2}{k^2} P \int_{-\infty}^{\infty} du \frac{du g(u)}{u - \omega/k}
$$

$$
= 1 - \frac{\omega^2}{k^2} P \int_{-\infty}^{\infty} du \frac{d_u g(u)}{u - u_0}
$$

(6.125)

If in the numerator of the integrand we subtract zero, in the form of $0 = d_u g(u_0)$, we can write

$$
\epsilon_\tau = 1 - \frac{\omega^2}{k^2} P \int_{-\infty}^{\infty} du \frac{d_u [g(u) - g(u_0)]}{u - u_0}
$$

(6.126)

Fig. 6.22 A contour $c_\epsilon$ that indicates one unstable mode.
We can integrate (6.126) by parts, because all quantities are well defined at the singularity, to obtain

$$\epsilon_i(\omega = ku_0) = 1 + \frac{\omega_e^2}{k^2} \int_{-\infty}^{\infty} du \frac{[g(u_0) - g(u)]}{(u - u_0)^2}$$  (6.127)

where the principal value symbol is no longer needed. The integrand in (6.127) is positive definite, since $g(u_0)$ is the maximum value of $g$. Thus, (6.127) yields

$$\epsilon_i(\omega = ku_0) > 1$$  (6.128)

so that the picture of $c_i$ is as shown in Fig. 6.24, confirming our prediction that the origin is not encircled and that there is no instability for a single-humped distribution. This result is known as Gardner’s theorem [3, 10].

In interpreting this result we must remember that $g(u)$ includes an ion contribution as well as an electron contribution. Thus, one situation in which the above result holds is when a single humped electron distribution is moving through a background of infinitely massive ions; when $m_i \to \infty$, (6.22) shows that $g(u)$ depends only on the electron distribution.

Next, consider the case where the distribution has a double hump, with a relative minimum between them (Fig. 6.25). Then (6.45) predicts three values of $\omega_i$.
\( \omega = ku_1, \omega = ku_0, \text{ and } \omega = ku_2; \) where \( c_\epsilon \) crosses the real axis. If the absolute maximum of \( g(u) \) occurs at \( u = u_1 \), then it is straightforward to show that 
\[ \epsilon(\omega = ku_1) > 1. \]

**EXERCISE** Verify this, using the same argument as in (6.127) and (6.128).

It furthermore must be the case that as we move along the \( \omega \) contour from \( \omega = -\infty \) to \( \omega = +\infty \), we encounter the crossings of the real \( \epsilon \)-axis in the order \( \epsilon(\omega = ku_1), \epsilon(\omega = ku_0), \) and then \( \epsilon(\omega = ku_2) \). Thus, the first part of \( c_\epsilon \) looks as shown in Fig. 6.26. We are now allowed two more crossings of the real \( \epsilon \)-axis. One possibility is as shown in Fig. 6.27, which does not give instability. Another possibility is shown in Fig. 6.28, which indicates one unstable root. We see that a necessary condition for instability is
\[ \epsilon(\omega = ku_0) < 0 \] (6.129)

which from (6.45) is
\[ \epsilon(\omega = ku_0) = 1 - \frac{\omega_1^2}{k^2} P \int_{-\infty}^{\infty} \frac{du}{u - u_0} g(u) \] (6.130)
By once again subtracting \( 0 = d_0 g(u_0) \) in the numerator, we can integrate by parts to obtain
\[
e(\omega = ku_0) = 1 + \frac{\omega c}{k^2} \int_{-\infty}^{\infty} du \frac{[g(u_0) - g(u)]}{(u - u_0)^2}
\]
(6.131)
where the justification is the same as in (6.127). Now (6.129) says we need \( e(\omega = ku_0) < 0 \) for instability. But this will be assured if
\[
\int_{-\infty}^{\infty} du \frac{[g(u_0) - g(u)]}{(u - u_0)^2} < 0
\]
(6.132)
for when (6.132) is true, (6.131) ranges from $\epsilon(\omega = ku_0) = 1$ for $k \to \infty$ to $\epsilon(\omega = ku_0) = -\infty$ for $k \to 0$. Thus, for some value of $k$, we must have $\epsilon(\omega = ku_0) < 0$ while $\epsilon(\omega = ku_2) > 0$, which is the necessary condition for instability. Equation (6.132) is called the Penrose criterion [11, 12]; it is a necessary and sufficient condition for the linear instability of a Vlasov–Poisson equilibrium.

Consider the integration in (6.132) as applied to the three regions shown in Fig. 6.29. In all of region $B$ the integrand is negative, while in regions $A$ and $C$ the integrand is positive. Thus, the negative contribution in $B$ must exceed the positive contributions from $A$ and $C$ in order that the Penrose criterion be satisfied. Notice that the negative contribution in $B$ is enhanced by a deep hole.

**EXERCISE** Show that if $g(u_0) = 0$, the Penrose criterion is always satisfied.

The Nyquist method also tells us the range of unstable wave numbers. By requiring $\epsilon(\omega = ku_0) < 0$ and $\epsilon(\omega = ku_2) > 0$, we find that Eq. (6.131) for
g(u)

\[ u \]

\[ v_{\text{drift}} \]

\[ v_e \]

\[ \text{Fig. 6.31 Two drifting Maxwells with } v_{\text{drift}} < v_e \text{ that are stable.} \]

\[ \varepsilon(\omega - ku_0) \text{ and the equivalent expression for } \varepsilon(\omega - ku_z) \text{ yield} \]

\[ \omega_e^2 \int_{-\infty}^{\infty} du \frac{[g(u) - g(u_2)]}{(u - u_2)^2} < k^2 < \omega_e^2 \int_{-\infty}^{\infty} du \frac{[g(u) - g(u_0)]}{(u - u_0)^2} \]

(6.133)

for the range of unstable wave number.

We have seen that the Penrose criterion needs a deep enough hole to predict instability. Thus, two weakly drifting Maxwellian groups of electrons will be unstable only when, crudely, the drift velocity equals the thermal speed, as indicated in Figs. 6.30 and 6.31.

Other cases of stability or lack thereof will be explored in the problems.

**6.10 GENERAL THEORY OF LINEAR VLASOV WAVES**

In preceding sections we have discussed linear electrostatic waves in the context of the Vlasov and Poisson equations; there was no background magnetic field. We found Langmuir waves and ion-acoustic waves, and we found a new physical effect, Landau damping. Let us now include a background magnetic field, and set up an approach that will yield all linear waves, including electromagnetic waves. Several new effects will appear. One of these is *cyclootron damping*, which is the magnetized analogue of Landau damping.

The basic equation is the Vlasov equation,

\[ \partial_t f_s + v \cdot \nabla_x f_s + \frac{q_s}{m_s} \left( E + \frac{v}{c} \times B \right) \cdot \nabla_v f_s = 0 \]  

(6.134)

where \( E(x,t) \) and \( B(x,t) \) can have internal and external contributions. Linearizing (6.134) about a time and space independent, zero order distribution function, \( f_s(x,v,t) = f_{so}(v) + f_{so}(x,v,t) \), we have

\[ \frac{q_s}{m_s} \left( E_0 + \frac{v}{c} \times B_0 \right) \cdot \nabla_v f_{so}(v) = 0 \]  

(6.135)

for each species, and
Vlasov Equation

\[ \frac{\partial f_{s_1}}{\partial t} + \mathbf{v} \cdot \nabla_{\mathbf{r}} f_{s_1} + \frac{q_s}{m_s} \left( \mathbf{E}_0 + \frac{\mathbf{v}}{c} \times \mathbf{B}_0 \right) \cdot \nabla_{\mathbf{v}} f_{s_1} = - \frac{q_s}{m_s} \left( \mathbf{E}_1 + \frac{\mathbf{v}}{c} \times \mathbf{B}_1 \right) \cdot \nabla_{\mathbf{v}} f_{s_0} \]  

(6.136)

The total charge density is

\[ \rho(x,t) = \sum_s q_s \int d^3 v f_{s_1}(x,\mathbf{v},t) \]  

(6.137)

while the total current is

\[ \mathbf{J}(x,t) = \sum_s q_s \int d^3 v \mathbf{v} f_{s_1}(x,\mathbf{v},t) \]  

(6.138)

where we have taken the zero order charge density and current to vanish. Combining (6.135) to (6.138) with Maxwell’s equations

\[ \nabla \cdot \mathbf{E}_1 = 4\pi \rho \]  

(6.139)

\[ \nabla \times \mathbf{E}_1 = - \frac{1}{c} \frac{\partial \mathbf{B}_1}{\partial t} \]  

(6.140)

\[ \nabla \cdot \mathbf{B}_1 = 0 \]  

(6.141)

and

\[ \nabla \times \mathbf{B}_1 = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{\partial \mathbf{E}_1}{\partial t} \]  

(6.142)

we have a complete set of linear equations with which to find the dispersion relation for an arbitrary linear wave.

Let us now solve the first order Vlasov equation (6.136). Recall that in Section 6.2 we introduced the concept of unperturbed orbits of hypothetical particles, so that the zero order Vlasov equation (6.135) could be written

\[ \frac{D}{D\tilde{t}} f_{s_0}(\mathbf{v}) = 0 \]  

(6.143)

We then proceeded to find equilibrium distribution functions that were functions of the constants of motion of the hypothetical particles. Consider a hypothetical particle moving in a given force field, consisting of zero order electric and magnetic fields. For the present, we allow the zero order electric and magnetic fields to be functions of both space and time; later we will make them constant. From Newton’s laws of motion we can follow the orbit of a particle to find \( \mathbf{X}(t) \), its orbit in real space, and \( \mathbf{V}(t) \), its orbit in velocity space. The equations for these variables are

\[ \dot{\mathbf{X}}(t) = \mathbf{V}(t) \]  

(6.144)

and

\[ \dot{\mathbf{V}}(t) = \frac{q_s}{m_s} \left\{ \mathbf{E}_0[X(t),t] + \frac{\mathbf{V}(t)}{c} \times \mathbf{B}_0[X(t),t] \right\} \]  

(6.145)

In particular, we associate one of these orbits with every point \((\mathbf{x},\mathbf{v},t)\) in seven-dimensional phase space, by choosing the appropriate constant of integration. That is, we choose
\[ X(t') = x - \int_{t'}^{t''} \dot{X}(t'') \, dt'' \]  

(6.146)

or

\[ X(t') = x - \int_{t'}^{t''} V(t'') \, dt'' \]  

(6.147)

which satisfies (6.144) and also has the property that

\[ X(t) = x \]  

(6.148)

Similarly, for velocity, we choose the constant of integration such that

\[ V(t') = v - \int_{t'}^{t''} \dot{V}(t'') \, dt'' \]  

(6.149)

Thus, the orbit \([X(t'), V(t')]\) is the orbit of that particle which reaches the position \((x, v)\) at time \(t\).

Consider any function \(h(x, v, t)\) Then

\[
\frac{d}{dt'} \left[ h(x', v', t') \right] \bigg|_{x=X(t')}^{v=V(t')} = \frac{\partial h}{\partial t'} \left( x', v', t' \right) \bigg|_{x=X(t')}^{v=V(t')} + \dot{X}(t') \cdot \nabla_x h(x', v', t') \bigg|_{x=X(t')}^{v=V(t')} + \dot{V}(t') \cdot \nabla_v h(x', v', t') \bigg|_{x=X(t')}^{v=V(t')} \]

(6.150)

Along the unperturbed orbit, we have \(\dot{X}(t') = V(t') = v'\), and

\[ \dot{V}(t') = \frac{q_s}{m_s} \left\{ E_0[X(t'), t'] + \frac{V(t')}{c} \times B_0[X(t'), t'] \right\} \]  

(6.151)

Thus, the right side of (6.150) is just the left side of (6.136) when \(h = f_{x1}\), and we can write (6.136) as

\[
\frac{d}{dt'} f_{x1}(x', v', t') \bigg|_{x=X(t')}^{v=V(t')} = - \frac{q_s}{m_s} \left\{ E_1[X(t'), t'] \right. \\
+ \frac{V(t')}{c} \times B_1[X(t'), t'] \bigg. \right\} \cdot \nabla_v f_{x1}(x', v', t') \bigg|_{x=X(t')}^{v=V(t')} \]

(6.152)

Both sides of (6.152) can be integrated from \(t' = -\infty\) to \(t' = t\) along the unperturbed orbit that ends up at \(X(t) = x\) and \(V(t) = v\). The result is

\[
f_{x1}(x, v, t) = f_{x1}[X(t'), V(t'), t' = -\infty] - \frac{q_s}{m_s} \int_{-\infty}^{t} dt' \left\{ E_1[X(t'), t'] + \frac{V(t')}{c} \times B_1[X(t'), t'] \right\} \\
\cdot \nabla_v f_{x1}(x', v', t') \bigg|_{x=X(t')}^{v=V(t')} \]

(6.153)
Equation (6.153) is a formal solution for \( f_{21} \), where in the integrand we must evaluate \( \mathbf{E}_1, \mathbf{B}_1, \) and \( f_{s0} \) at the correct point of the unperturbed orbit \([X(t'), V(t')]\) of the hypothetical particle at time \( t' \). From now on, we consider only uniform, stationary zero order fields \( \mathbf{E}_0 = 0, \mathbf{B}_0 = \text{constant} \), and \( f_{s0} = f_{s0}(v) \) a function only of velocity, although (6.153) can be used in more general cases.

Let us look for plane wave solutions to (6.153),

\[
\mathbf{E}_t(x,t) = \bar{\mathbf{E}} \exp(-i\omega t + ik \cdot x) \tag{6.154}
\]

\[
\mathbf{B}_t(x,t) = \bar{\mathbf{B}} \exp(-i\omega t + ik \cdot x) \tag{6.155}
\]

and

\[
f_{s1}(x,v,t) = \bar{f}_s(v) \exp(-i\omega t + ik \cdot x) \tag{6.156}
\]

where \( \bar{\mathbf{E}} \) and \( \bar{\mathbf{B}} \) are constant vectors. For the moment, we take \( \text{Im}(\omega) > 0 \), so the wave is exponentially growing with respect to time. Then a finite amplitude at time \( t \) implies \( f_{s1}(t' = -\infty) = 0 \), and we can ignore the contribution of \( f_{s1}(t' = -\infty) \) in (6.153). The philosophy here is to find a dispersion relation valid for \( \text{Im}(\omega) > 0 \), and then to analytically continue the dispersion relation for arbitrary \( \omega \). This is the same technique used earlier for Langmuir waves, which led in that case to the Landau contour for evaluating the electrostatic dispersion relation.

Equation (6.153) now reads

\[
\bar{f}_s(v) \exp(-i\omega t + ik \cdot x) = -\frac{q_s}{m_s} \int_{-\infty}^{t'} dt' \left[ \bar{\mathbf{E}} + \frac{V(t')}{c} \times \bar{\mathbf{B}} \right] \cdot \nabla_v f_{s0}(v') \big|_{v = V(t')} \exp \left[ -i\omega t' + ik \cdot X(t') \right] \tag{6.157}
\]

Moving \( \exp(-i\omega t + ik \cdot x) \) to the right we find

\[
\bar{f}_s(v) = -\frac{q_s}{m_s} \int_{-\infty}^{t'} dt' \left[ \bar{\mathbf{E}} + \frac{V(t')}{c} \times \bar{\mathbf{B}} \right] \cdot \nabla_v f_{s0}(v') \big|_{v = V(t')} \exp \left[ -i\omega t' + ik \cdot [X(t') - x] \right] \tag{6.158}
\]

Making the change of variable \( \tau = t' - t \) we have

\[
\bar{f}_s(v) = -\frac{q_s}{m_s} \int_{-\infty}^{0} d\tau \left[ \bar{\mathbf{E}} + \frac{V(\tau)}{c} \times \bar{\mathbf{B}} \right] \cdot \nabla_v f_{s0}(v') \big|_{v(\tau)} \exp \left[ -i\omega \tau + ik \cdot [X(\tau) - x] \right] \tag{6.159}
\]

where we realize that in this notation, \([X(\tau), V(\tau)]\) is the orbit that yields \([X(\tau = 0), V(\tau = 0)] = (x,v)\).

### 6.11 Linear Vlasov Waves in Unmagnetized Plasma

Let us evaluate (6.159) for the case of an equilibrium plasma with no zero order fields. Then the unperturbed orbits are from (6.147) and (6.149):

\[
V(t') = v \tag{6.160}
\]

and

\[
X(t') = x - v(t - t') = x + vt \tag{6.161}
\]

\[
V(t') = v \tag{6.160}
\]

and

\[
X(t') = x - v(t - t') = x + vt \tag{6.161}
\]
Since \( V(\tau) \) does not depend on \( \tau \), (6.159) becomes
\[
\tilde{f}_s(v) = -\frac{q_s}{m_s} \left( \vec{E} + \frac{v}{c} \times \vec{B} \right) \cdot \nabla_v f_{s0}(v) \\
\times \int_{-\infty}^{0} d\tau \exp \left( -i\omega \tau + i\mathbf{k} \cdot \mathbf{v} \tau \right)
\]
(6.162)
Since \( \text{Im}(\omega) > 0 \), the integral is well behaved and we find
\[
\int_{-\infty}^{0} d\tau \exp \left( -i\omega \tau + i\mathbf{k} \cdot \mathbf{v} \tau \right) = \frac{1}{i(\omega - \mathbf{k} \cdot \mathbf{v})}
\]
(6.163)
so that
\[
\tilde{f}_s(v) = \frac{(q_s/m_s)}{i(\omega - \mathbf{k} \cdot \mathbf{v})} \left( \vec{E} + \frac{v}{c} \times \vec{B} \right) \cdot \nabla_v f_{s0}(v)
\]
(6.164)
Taking \( \vec{B} = 0 \) and looking for electrostatic waves, we could combine (6.164) for each species with Poisson’s equation to obtain our old Vlasov-Poisson dispersion relation, leading to Langmuir waves, ion-acoustic waves, and Landau damping.

Taking \( \mathbf{B}_i(x,t) = \vec{B} \exp (-i\omega t + i\mathbf{k} \cdot \mathbf{x}) \neq 0 \), we find from Ampere’s law (6.142) and Faraday’s law (6.140) that
\[
i\mathbf{k} \times \mathbf{E}_1 = \frac{i\omega}{c} \mathbf{B}_1
\]
(6.165)
and
\[
i\mathbf{k} \times \mathbf{B}_1 = \frac{4\pi}{c} \mathbf{J} - \frac{i\omega}{c} \mathbf{E}_1
\]
(6.166)
or
\[
c^2[\mathbf{k} \times (\mathbf{k} \times \mathbf{E}_1)] = -i4\pi c \mathbf{J} - \omega^2 \mathbf{E}_1
\]
(6.167)
For isotropic zero order distribution functions \( f_{s0}(v) = f_{s0}(v) \), the term \( (\mathbf{v} \times \vec{B}) \cdot \nabla_v f_{s0} \) in (6.164) vanishes.

**EXERCISE** Verify this.

Then
\[
\mathbf{J}(x,t) = \sum_s q_s \int dv \mathbf{v} f_{s1}(x,\mathbf{v},t)
\]
\[
= \sum_s q_s \exp (-i\omega t + i\mathbf{k} \cdot \mathbf{x}) \int dv \frac{q_s}{m_s} \frac{\vec{E} \cdot \nabla_v f_{s0}(v)}{i(\omega - \mathbf{k} \cdot \mathbf{v})} \mathbf{v}
\]
(6.168)
Let us look for transverse waves, such that \( \vec{E} \perp \mathbf{k} \). Then \( \mathbf{k} \times (\mathbf{k} \times \vec{E}) = -k^2 \vec{E} \), and (6.167) becomes
\[
(\omega^2 - k^2c^2)\vec{E} = -4\pi i\omega \sum_s q_s^2 \sum_{m_s} \int dv \frac{\vec{E} \cdot \nabla_v f_{s0}(v)}{i(\omega - \mathbf{k} \cdot \mathbf{v})} \mathbf{v}
\]
(6.169)
where the harmonic dependence has been factored out. Suppose the vectors are arranged as shown in Fig. 6.32. Then the numerator in (6.169) has a term \( \vec{E} \cdot \nabla_v = \).
\[ \vec{E} \cdot \vec{v}_i, \text{ while the denominator is of the form } \omega - kv_x. \text{ Thus, we can integrate by parts in the numerator, picking out only the term } \vec{E} \cdot \vec{v}_i = \vec{E} \cdot \vec{0} = \vec{E}. \text{ We find} \]

\[ (\omega^2 - k^2c^2)\vec{E} = 4\pi \omega \vec{E} \frac{e^2}{m} n_0 \int dv_x \frac{g(v_x)}{\omega - kv_x} \]

(6.170)

where \( g(v_x) \) is as usual defined by (6.22) and where we have ignored the ion dependence by allowing \( m_i \rightarrow \infty \). Dividing out the constant vector \( \vec{E} \), we finally obtain the dispersion relation for electromagnetic waves in unmagnetized plasma,

\[ \omega^2 = k^2c^2 + \omega_i^2 \omega \int_{-\infty}^{\infty} dv_x \frac{g(v_x)}{\omega - kv_x} \]

(6.171)

Whenever there might be a problem with the pole in (6.171), the Landau contour must be used, for the same reason as in the discussion of Langmuir waves. The integral in (6.171) can easily be performed with the assumption \( \omega/k \gg v_x \) for all \( v_x \) of interest. Then \( \omega - kv_x \approx \omega_i \), the integral \( \int_{-\infty}^{\infty} dv_x g(v_x) = 1 \), and we find

\[ \omega^2 = \omega_i^2 + k^2c^2 \]

(6.172)

for linear electromagnetic waves in unmagnetized plasma.

**EXERCISE** Show from (6.172) that even in a more accurate treatment of the integral in (6.171), there is no need to consider a contribution involving \( g(v_x)|_{v_x=\omega/k} \).

In this section we have seen how electrostatic and electromagnetic waves in a uniform plasma with no external fields are treated via the Vlasov equation. In the next section we shall set up the equivalent procedure for a uniformly magnetized plasma.

### 6.12 LINEAR VLASOV WAVES IN MAGNETIZED PLASMA

In the previous section we have seen that the linearized Vlasov equation can be solved by integrating along the orbits of hypothetical particles moving in the zero
order fields; these orbits are called unperturbed because they do not feel the effect of the wave motion for which one is looking. In an unmagnetized plasma, the unperturbed orbits are simple, and it is straightforward to evaluate the perturbed distribution function. Consider the evaluation of (6.159) in the presence of a uniform background magnetic field. Now the unperturbed orbits are spirals around the magnetic field lines, satisfying Newton’s law

$$m_e \dot{V}(\tau) = \frac{q_e}{c} \mathbf{v}(\tau) \times \mathbf{B}_0$$ \hspace{1cm} (6.173)

Choosing the magnetic field in the $\hat{z}$-direction, the gyro-orbits that satisfy $\mathbf{X}(\tau = 0) = \mathbf{x}, \mathbf{V}(\tau = 0) = \mathbf{v}$, are

$$V_z(\tau) = v_z$$ \hspace{1cm} (6.174)

$$Z(\tau) = z + v_z \tau$$ \hspace{1cm} (6.175)

$$V_x(\tau) = v_{\perp} \cos(\varphi - \Omega_s \tau)$$ \hspace{1cm} (6.176)

$$X(\tau) = x - \frac{v_{\perp}}{\Omega_s} \sin(\varphi - \Omega_s \tau) + \frac{v_{\perp}}{\Omega_s} \sin \varphi$$ \hspace{1cm} (6.177)

$$V_y(\tau) = v_{\perp} \sin(\varphi - \Omega_s \tau)$$ \hspace{1cm} (6.178)

and

$$Y(\tau) = y + \frac{v_{\perp}}{\Omega_s} \cos(\varphi - \Omega_s \tau) - \frac{v_{\perp}}{\Omega_s} \cos \varphi$$ \hspace{1cm} (6.179)

where the gyrofrequency is $\Omega_s \equiv q_e B_o / m_e c$, and $\varphi$ is a constant $0 \leq \varphi \leq 2\pi$.

**EXERCISE** Verify that (6.174) to (6.179) satisfy (6.173) with the appropriate boundary conditions.

Inserting the orbit (6.174) to (6.179) into (6.159), we can carry out the integration over $\tau$ in (6.159). Then using Maxwell’s equations to eliminate $\mathbf{B}$ in terms of $\mathbf{E}$, we could obtain a general dispersion relation for waves in a uniformly magnetized plasma. This dispersion relation would contain all of the waves to be encountered in the next chapter on fluid theory, for example, Alfvén waves, upper-hybrid waves, and extraordinary waves. In addition, entirely new wave modes appear in the Vlasov formulation, which are impossible to obtain from a fluid formulation. Known as Bernstein modes, these waves depend on the detailed interaction of the wave motion with the gyro-orbits of the particles.

Because the details of the evaluation of (6.159) are quite tedious (see [13], p. 405 and [14] and [15]), we shall simply sketch the derivation and point to the physically interesting terms. For the zero order distribution, we choose the natural function of the constants of the motion $f_{s0} = f_{s0}(v_{\perp}, v_z)$. Then with $v_{\perp} = (v_{x}^2 + v_{y}^2)^{1/2}$ we have

$$\nabla_V f_{s0}(v_{\perp}, v_z) |_{v = V(r')} = \hat{x} \partial_{v_x} f_{s0} + \hat{y} \partial_{v_y} f_{s0} + \hat{z} \partial_{v_z} f_{s0} |_{v = V(r')}$$

$$= (V_x \hat{x} - V_y \hat{y}) \frac{1}{v_{\perp}} \partial_{v_{\perp}} f_{s0} + \hat{z} \partial_{v_z} f_{s0}$$ \hspace{1cm} (6.180)

**EXERCISE** Verify this equation.
Every term in (6.180), except \( V_x \) and \( V_y \), is a constant of motion of a particle orbit and can be taken outside the integration in (6.159). In general, the perturbed magnetic field \( \mathbf{B} \) can have three components. However, the combination
\[
(\mathbf{V} \times \mathbf{B}) \cdot \nabla_v f_{s0} = \left( -V_x v_x \mathbf{B}_y + v_y V_y \mathbf{B}_x \right) \frac{1}{v_\perp} \partial_{v_\perp} f_{s0}
+ (V_x \mathbf{B}_y - \mathbf{B}_x V_y) \partial_{v_\parallel} f_{s0}
\]
has only single terms, \( V_x, V_y \) that depend on \( \tau \) and must be kept inside the integral. After taking the constants \( \mathbf{E} \) and \( \mathbf{B} \) (expressed in terms of \( \mathbf{E} \) through Maxwell's equations if desired) as well as \( v_\perp \) and \( f_{s0}(v_\perp, v_\parallel) \) outside the integral, all remaining terms are of the form
\[
I = \int_0^\infty d\tau \begin{bmatrix} V_x(\tau) \\ V_y(\tau) \\ 1 \end{bmatrix} \exp \left\{ -i\omega \tau + i \mathbf{k} \cdot [\mathbf{X}(\tau) - \mathbf{x}] \right\}
\]
(6.182)
The integrals (6.182) can be evaluated in terms of the identities
\[
e^{ia \sin \theta} = \sum_{n=-\infty}^{\infty} J_n(a) \exp (in\theta)
\]
(6.183)
and
\[
e^{-ia \sin \theta} = \sum_{n=-\infty}^{\infty} J_n(a) \exp (-in\theta)
\]
(6.184)
where \( J_n \) is the Bessel function of order \( n \). Without loss of generality, we choose the wave number to be \( \mathbf{k} = k_x \mathbf{x} + k_z \mathbf{z} \); then (6.175) and (6.177) yield
\[
\mathbf{k} \cdot [\mathbf{X}(\tau) - \mathbf{x}] = k_z v_z \tau
- \frac{k_z v_\perp}{\Omega_z} \sin (\varphi - \Omega_z \tau) + \frac{k_x v_\perp}{\Omega_z} \sin \varphi
\]
(6.185)
Thus, choosing the factor unity in (6.182) as an example, (6.182) becomes
\[
I = \int_0^\infty d\tau e^{-i\omega \tau + ik_x v_x \tau} e^{-ia \sin (\omega - \Omega_z \tau)} e^{ia \sin \varphi}
\]
(6.186)
where \( a \equiv k_z v_\perp / \Omega_z \). With (6.183) and (6.184) we have
\[
I = \int_0^\infty d\tau e^{-i(\omega \tau + ik_x v_x \tau) \sum_{n=-\infty}^{\infty} J_n(a)}
\times e^{-i(\varphi + i\Omega_z \tau) \sum_{n=-\infty}^{\infty} J_n(a) e^{in\varphi}}
\]
(6.187)
The integration can now be performed because only three exponential factors depend on \( \tau \). We find
\[
I = \sum_{n=-\infty}^{\infty} J_n(a) \sum_{m=-\infty}^{\infty} J_m(a) e^{i(n-m)\varphi} \frac{1}{-i(\omega - i\Omega_z - k_z v_z)}
\]
(6.188)
A glance back at (6.159) shows that we have just calculated the term involving \( \mathbf{E}_z \partial_{v_z} f_{s0}(v_\perp, v_\parallel) \); this term is therefore
where \( a \equiv k_z v_z / \Omega \). The other terms in (6.189) are no harder to calculate than the one shown; for example, the integral (6.182) involving \( V_{x}(\tau) = v_{x} \cos (\varphi - \Omega_{e} \tau) \) is easily calculated using \( V_{x}(\tau) = v_{x} [\exp (i \varphi - i \Omega_{x} \tau) + \exp (-i \varphi + i \Omega_{x} \tau)] / 2 \), which fits naturally into the form (6.187) and has the effect of shifting the indices of the Bessel functions up and down by one. Eliminating the perturbed magnetic field using Maxwell’s equations, we find as in the previous section [Eqs. (6.167), (6.169)]

\[
\omega^{2} \mathbf{E} + c^{2} [\mathbf{k} \times (\mathbf{k} \times \mathbf{E})] = -4 \pi i \omega \sum_{s} q_{s} \int_{L} d^{3} v \vec{f}_{s}(v) \tag{6.190}
\]

where \( \vec{f}_{s}(v) \) from (6.189) is linearly proportional to the various components of \( \mathbf{E} \). Thus, (6.190) is three equations in three unknowns: setting the determinant of the coefficients equal to zero yields the horrendous dispersion relation found in Ref. 13, Eqs. (8.10.10) and (8.10.11). In (6.190), the velocity integral must, as usual, be performed along the Landau contour.

By taking appropriate limits, we could obtain from (6.190) all of the waves of fluid theory. In addition, there occur waves called Bernstein modes [16]. These modes propagate across the magnetic field, so that \( k_{z} \to 0 \) in the denominator of (6.189), and are predominantly electrostatic. Then the denominator can be taken outside the integral of (6.189), and the dispersion relation will contain sums of terms like \( (\omega - l \Omega_{e})^{-1} \). This term goes from \( -\infty \) to \( +\infty \) as \( \omega \) changes by a small amount \( \Omega_{e} \). The result is a set of modes, one for each harmonic of the cyclotron frequency of each species. One of these modes corresponds to the upper-hybrid mode (see Chapter 7) in the limit of small wave number. The dispersion diagram is qualitatively as shown in Fig. 6.33. This figure is for the case \( \omega_{uH} = (\Omega_{e}^{2} + \omega_{i}^{2})^{1/2} \) between \( 2|\Omega_{e}| \) and \( 3|\Omega_{e}| \). Notice that there are waves for any frequency such that \( |\Omega_{e}| < \omega < \omega_{uH} \), but that for \( \omega > \omega_{uH} \) there are “stop” bands where no waves exist.

There are other interesting features of (6.189) and (6.190). Recall that in the unmagnetized case, Landau damping came from a resonant denominator of the form \((\omega - kv)^{-1}\), representing strong interaction with particles with speeds equal to the wave phase speed, \( v = \omega / k \). From (6.189), we get the same kind of resonant denominator, but involving only the component of velocity \( v_{z} \) along the magnetic field. The same procedure as in the unmagnetized case will yield damping involving those particles with parallel speeds

\[
v_{z} \approx \frac{\omega - l \Omega_{e}}{k_{z}}, \quad l = 0, \pm 1, \pm 2, \ldots \tag{6.191}
\]

If \( k_{z} \to 0 \), and \( \omega \neq l \Omega_{e} \) for any \( l \), there is no damping.
When \( l = 0 \) in (6.191), we have our old friend Landau damping. When \( l \neq 0 \), we have **cyclotron damping**. Physically, cyclotron damping occurs when the particle sees a wave whose Doppler shifted frequency is the gyrofrequency or some harmonic thereof:

\[
\omega - k_z v_z = l \Omega_z, \quad l = \pm 1, \pm 2, \ldots
\]  

(6.192)

Suppose the wave is circularly polarized, or has at least one component that is circularly polarized. For example, consider \( l = 1 \). Then the particle might see the field shown in Fig. 6.34 as it goes around its gyro-orbit. Evidently, the particle can be continuously accelerated and thus the wave is damped.

The concept of cyclotron damping has an interesting extension to relativistic plasmas. Then \( \Omega_z = q_z B_0 / m_z c \) is a function of particle speed, since the relativistic
mass is a function of particle speed. The resonance condition (6.192) then depends on \( v_\perp \) as well as \( v_z \).

This completes our discussion of linear waves in uniform Vlasov plasma. In the next section, we encounter our first example of a nonlinear wave.

### 6.13 BGK MODES

In preceding sections we have studied the linear waves that can exist in a Vlasov plasma. As the intensity of such waves is increased, nonlinear effects that are ignored in the linear derivation become important. There are many different nonlinear effects, and much current research in plasma physics is devoted to the theoretical, experimental, and numerical study of nonlinear waves. In this section, we introduce an important class of nonlinear waves, the **BGK modes**, named after Bernstein, Greene, and Kruskal [6].

In Case C of Section 6.2 we encountered an equilibrium distribution function in the presence of a spatially varying electrostatic potential. A BGK mode involves just such a distribution function, where the electrostatic potential is produced self-consistently by the distribution function through Poisson's equation.

For simplicity, let us consider the time independent situation with spatial variation only in the \( x \)-direction. Then for each species the Vlasov equation is

\[
\left( v \frac{\partial}{\partial x} - \frac{q_s}{m_s} \frac{d\varphi}{dx} \frac{\partial}{\partial v} \right) f_s(x,v) = 0
\]

where \( v \equiv v_\perp \). The potential \( \varphi(x) \) must be determined self-consistently through Poisson's equation

\[
\frac{\partial^2 \varphi}{\partial x^2} = 4 \pi e \left[ \int_{-\infty}^{\infty} dv f_s(x, v) - \int_{-\infty}^{\infty} dv f(x, v) \right]
\]

where it is understood that the \( v_\parallel \) and \( v_z \) dependencies of \( f_s(x, v) \) have been integrated over. We already know the solutions of (6.193); these are just the equilibrium distribution functions (6.12). Thus, we can pick two arbitrary functions \( f_s[v_\perp^2 + 2q_s \varphi(x)/m_s, v_z] \), one for each species, insert these in (6.194), and solve the resulting equation, which is

\[
\frac{\partial^2 \varphi}{\partial x^2} = 4 \pi e \int_{-\infty}^{\infty} dv \left\{ f_s \left[ v_\perp^2 - 2e \varphi(x)/m_e \right] \right. \\
- f_e \left[ v_\perp^2 + 2e \varphi(x)/m_e \right]
\]

This equation must be solved for \( \varphi(x) \) subject to appropriate boundary conditions. For example, we may wish to look for periodic wavelike solutions, or for localized soliton solutions. It turns out that there exists a huge number of solutions to the nonlinear integro-differential equation (6.195).

Let us begin to study (6.195) by looking at a very simple case, where each species is a cold beam of particles, each particle of species \( s \) having the same speed at a given position. Thus, we choose

\[
f_s(x, v) = 2n_0 v_\perp \delta[v_\perp^2 - 2e \varphi(x)/m_e - v_\perp^2]
\]
where for definiteness we choose only the positive root inside the delta function; that is, we recall the relation
\[
\delta[f(y)] = \frac{\delta(y - y_0)}{\left| \frac{df}{dy} \right|_{y=y_0}} \tag{6.197}
\]
where \(y_0\) is the solution of \(f(y_0) = 0\). Then (6.196) becomes
\[
f_e(x, u) = n_0 \frac{\nu_e}{\bar{v}_e} \delta(u - \bar{v}_e) \tag{6.198}
\]
where
\[
\bar{v}_e(x) = \left[ \nu_e^2 + 2e\varphi(x)/m_e \right]^{1/2} \tag{6.199}
\]
Similarly, for the ions we take
\[
f_i(x, u) = n_0 \frac{\nu_i}{\bar{v}_i} \delta(u - \bar{v}_i) \tag{6.200}
\]
with
\[
\bar{v}_i(x) = \left[ \nu_i^2 - 2e\varphi(x)/m_i \right]^{1/2} \tag{6.201}
\]
Here, \(\nu_i\) and \(\nu_e\) are arbitrary constants that we choose large enough that (6.199) and (6.201) always yield real positive values for \(\bar{v}_e\) and \(\bar{v}_i\). We have chosen the normalization constants \(n_0\) the same for ions and electrons; we must check at the end of the calculation that this gives an overall neutral plasma.

We now look for spatially periodic solutions to (6.195). Integrating \(f_e, f_i\) over all velocity space, we find
\[
n_e(x) = n_0 \frac{\nu_e}{\bar{v}_e} \tag{6.202}
\]
and
\[
n_i(x) = n_0 \frac{\nu_i}{\bar{v}_i} \tag{6.203}
\]
so that (6.195) becomes
\[
\frac{d^2\varphi}{dx^2} = 4\pi n_0 e \left( \frac{\nu_e}{\bar{v}_e} - \frac{\nu_i}{\bar{v}_i} \right) \tag{6.204}
\]
or
\[
\frac{d^2\varphi}{dx^2} = 4\pi n_0 e \left\{ \left( 1 + \frac{2e\varphi(x)}{m_e\nu_e^2} \right)^{1/2} - \left( 1 - \frac{2e\varphi(x)}{m_i\nu_i^2} \right)^{1/2} \right\} \tag{6.205}
\]
We notice the fortunate circumstance that (6.205) is in the form of a pseudopotential equation; that is, it is in the form
\[
\frac{d^2\varphi}{dx^2} = -\frac{\partial}{\partial\varphi} V(\varphi) \tag{6.206}
\]
with
\[
V(\varphi) = -4\pi n_0 \left\{ m_e\nu_e^2 \left( 1 + \frac{2e\varphi}{m_e\nu_e^2} \right)^{1/2} + m_i\nu_i^2 \left( 1 - \frac{2e\varphi}{m_i\nu_i^2} \right)^{1/2} \right\} \tag{6.207}
\]
As a specific example, let us choose \( m, v_e^2 = m, v_l^2 \equiv T \). Then
\[
V(\varphi) = -4\pi n_0 T \left\{ \left(1 + \frac{2e\varphi}{T}\right)^{1/2} + \left(1 - \frac{2e\varphi}{T}\right)^{1/2} \right\}
\]  
(6.208)

The sketch of \( V(\varphi) \) is as shown in Fig. 6.35. Equations of the form (6.206) are called pseudopotential equations because of their resemblance to Newton's law of motion \( m\ddot{x} = F(x) = -dV(x)/dx \). With an initial choice of the "pseudoenergy" somewhere between \(-\left(32\right)^{1/2} \pi n_0 T\) and \(-8\pi n_0 T\), the "pseudoparticle" oscillates forever in the pseudopotential well, producing a spatially periodic potential that oscillates between \(-\varphi_0\) and \(\varphi_0\), as shown in Fig. 6.36. The function \( \varphi(x) \) is a periodic function but is not a sine function; it becomes a sine function in the limit of very small \(\varphi_0\).

In the limit of small \(\varphi_0\), we can make analytic progress by expanding the square roots in (6.205), assuming \(e\varphi(x)/T \ll 1\) for all \(x\). We obtain
\[
\frac{d^2\varphi}{dx^2} + \frac{8\pi n_0 e^2}{T} \varphi = 0
\]
(6.209)
with solution
\[
\varphi(x) = \varphi_0 \sin \left(2^{1/2} x/\lambda_{\text{eff}}\right)
\]
(6.210)
where we have defined an effective Debye length
\[
\lambda_{\text{eff}} = v_e/\omega_e
\]
(6.211)
Recall that \(v_e\) here is a constant and not a thermal speed.
Our physical picture of this BGK mode, both the nonlinear version (6.206) and the linear limit (6.210), is as follows. A spatially periodic potential exists. The ion beam is accelerated through regions of large negative potential and thus has a lower density there, while the electron beam is decelerated in regions of large negative potential and thus has a higher density there. The net result is a negative net charge in regions of negative potential, of exactly the right amount to produce the negative potential. The opposite argument produces the regions of positive potential. The potential and densities thus have the phase relationships shown in Fig. 6.37. The important point is that this physical process works not only in the linear regime of (6.210), but also the nonlinear regime of (6.206).

In the preceding discussion we assumed that the ion and electron velocities were large enough so that none of them were trapped in the electrostatic potential wells. In other words, we had ion energy $> e\varphi(x)$ for all $x$, and electron energy $> -e\varphi(x)$ for all $x$. We can also consider the case where some of the electrons or ions are trapped in the potential wells. Amazingly, it turns out that almost any potential $\varphi(x)$ can be constructed by choosing appropriate distributions of trapped electrons, untrapped electrons, trapped ions, and untrapped ions.

Fig. 6.37 Phase relationships among electrostatic potential, electron density, ion density, and net charge density in the BGK mode of Fig. 6.36.
For this discussion it is convenient to think in terms of distribution functions that depend on energy \( \mathcal{E} \) rather than distribution functions that depend on velocity \( v \). With the substitution \( \mathcal{E} = \frac{1}{2} m_s v^2 + q_s \phi \), we have \( d\mathcal{E} = m_s v \, dv = m_s [(2/m_s) (\mathcal{E} - q_s \phi)]^{1/2} \, dv \) and

\[
\frac{f_s(v) \, dv}{f_s(v(\mathcal{E})) \, dv} = \frac{\mathcal{E}}{(2m_s (\mathcal{E} - q_s \phi))^{1/2}} \tag{6.212}
\]

Equation 6.212 applies to particles with positive speeds. If we assume for convenience (we do not need to do this in general) that there are equal numbers of left-going and right-going particles, then we have

\[
n_s(x) = \int_{-\infty}^{\infty} dv \, f_s(x,v) = 2 \int_{0}^{\infty} dv \, f_s(x,v)
\]

\[
= 2 \int_{q_s \phi}^{\infty} d\mathcal{E} \frac{f_s(x,\mathcal{E})}{(2m_s (\mathcal{E} - q_s \phi))^{1/2}} \tag{6.213}
\]

where the lower limit of the energy integration must be taken to be \( q_s \phi \); no particle can have energy less than \( q_s \phi(x) \) for then its velocity would be imaginary since \( \frac{1}{2} m_s v^2 = \mathcal{E} - q_s \phi \).

Consider a periodic potential, as shown in Fig. 6.38. Then any ion with total energy \( \mathcal{E} \) less than \( e\phi_{\text{max}} \) will be trapped between the potential hills; the ion with energy \( e\phi_0 \) oscillates forever on the solid line shown. An ion with total energy \( \mathcal{E} \) greater than \( e\phi_{\text{max}} \) will travel forever to the left or to the right. The electrons, however, see the potential upside down, because of their negative charge. Thus, any electron with energy \( \mathcal{E} \) less than \( -e\phi_{\text{min}} \) will be trapped between the potential minima, while electrons with energies greater than \( -e\phi_{\text{min}} \) travel forever to the left or to the right.

Suppose we are given a completely arbitrary periodic potential \( \phi(x) \), a given distribution \( f_s(\mathcal{E}) \) of ions (both trapped and untrapped), and a given distribution \( f_s(\mathcal{E}) \), \( \mathcal{E} > -e\phi_{\text{min}} \). Then it turns out that the distribution of trapped electrons \( f_s(\mathcal{E}) \), \( -e\phi < \mathcal{E} < -e\phi_{\text{min}} \), can always be chosen so that Poisson's equation is satisfied and the given potential \( \phi(x) \) is indeed produced. Details of this calculation can be found on p. 436 of Ref. [13]. Note that \( f_s \) can be different for \( v < 0 \) and \( v > 0 \).

There are many practical applications of BGK modes, including the nonlinear stage of a Landau damped Langmuir wave (Section 6.8), and the theories of shock

---

**Fig. 6.38** Periodic potential of a BGK mode that contains trapped and untrapped particles.
waves and double layers. By contrast, the theory of Case-Van Kampen modes, to be presented in the next section, has very little practical application; nevertheless, this theory teaches us much about the analytic structure of the Vlasov equation.

6.14 CASE-VAN KAMPEN MODES

In Sections 6.1 to 6.5 we studied Langmuir waves and Landau damping by linearizing the Vlasov and Poisson equations, eliminating the perturbed distribution function $f_i$, and solving the initial value problem for the electric field $E$. This led us to look for normal modes of $E$, which were found by setting the dielectric function $\epsilon(\omega, k)$ equal to zero. In this way we found one normal mode for every value of $k$, with $\omega(k) = \omega_c(1 + \frac{1}{2} k^2 \lambda_e^2) + i \gamma$ where $\gamma$ is the Landau damping rate.

There is another way to approach this problem, and that is to eliminate $E$ and look for normal modes of $f_i$. In this way we find the Case-Van Kampen modes [17, 18].

The Vlasov-Poisson system is

$$\partial_t f + v \partial_x f - \frac{eE}{m} \partial_v f = 0$$  \hspace{1cm} (6.214)

and

$$\partial_x E = 4\pi e \left[ n_0 - \int_{-\infty}^{\infty} dv f(v) \right]$$  \hspace{1cm} (6.215)

where one-dimensional variations are considered, $v \equiv v_x$, and $f(v)$ is the one-dimensional electron distribution. Equation (6.214) refers to electrons only, the ions being fixed ($m_i \rightarrow \infty$). Linearizing (6.214) and (6.215) exactly as in Section 6.3 we find

$$\partial_t f_i + v \partial_x f_i = \frac{n_0 eE}{m} \frac{\partial g}{\partial v}$$  \hspace{1cm} (6.216)

and

$$\partial_x E(x, t) = -4\pi e \int_{-\infty}^{\infty} dv f_i(x, v, t)$$  \hspace{1cm} (6.217)

where $f_0(v) = n_0 g(v)$, $\int_{-\infty}^{\infty} dv g(v) = 1$. We can now look for normal modes of $f_i$ that have the spatial and time dependence $\exp(-i\omega t + ikx)$. Note that this is not the same procedure as used previously in Section 6.4 for the electric field $E$. There, we assumed only the spatial dependence $\exp(ikx)$, and used Laplace transform techniques to consider the complete time evolution. At late times, we found that only the normal modes given by the zeros of $\epsilon(\omega, k)$ were important. Here we are looking immediately for normal modes in space and time. We are not considering an initial value problem; the connection between the normal modes found here and an initial value problem must be established separately.

Looking for solutions $f_i(x, v, t) = \tilde{f}_i(v) \exp(-i\omega t + ikx)$, $E = E_0 \exp(-i\omega t + ikx)$, (6.216) and (6.217) become

$$(-i\omega + ikv)\tilde{f}_i = \frac{n_0 eE_0}{m} \frac{\partial g}{\partial v}$$  \hspace{1cm} (6.218)
and

$$E_0 = \frac{-4\pi e}{ik} \int_{-\infty}^{\infty} dv \, \tilde{f}_1(v)$$  \hspace{1cm} (6.219)

from which we can eliminate $E_0$ to obtain

$$\left( v - \frac{\omega}{k} \right) \tilde{f}_1 = \frac{\omega^2}{k^2} \frac{\partial g}{\partial v} \int_{-\infty}^{\infty} dv' \, \tilde{f}_1(v')$$  \hspace{1cm} (6.220)

Defining $\eta(v) = (\omega^2/k^2) \frac{\partial g}{\partial v}$, this is

$$\left( v - \frac{\omega}{k} \right) \tilde{f}_1(v) = \eta(v) \int_{-\infty}^{\infty} dv' \, \tilde{f}_1(v')$$  \hspace{1cm} (6.221)

Equation (6.221) is a linear integral equation for $\tilde{f}_1(v)$, with nonconstant coefficients (the $v$ on the left and the $\eta(v)$ on the right). One good approach to solving such equations is to guess the solution. We guess

$$\tilde{f}_1(v) = P \left[ \frac{\eta(v)}{v - \omega/k} \right] + \delta(v - \omega/k) \left[ 1 - P \int_{-\infty}^{\infty} \frac{\eta(v')}{v' - \omega/k} \, dv' \right]$$  \hspace{1cm} (6.222)

with which $f_1(x, v, t) = \tilde{f}_1(v) \exp(-i\omega t + ikx)$ is the Case–Van Kampen mode [17, 18]. In (6.222), $P$ stands for principal value, and is defined by

$$P \left( \frac{1}{x - a} \right) = \begin{cases} \frac{1}{x - a} & x \neq a \\ \lim_{x \to a^\pm} \frac{1}{x - a} & x = a \end{cases}$$  \hspace{1cm} (6.223)

so that this expression is either $+\infty$ or $-\infty$ at $x = a$, depending on from which side the limit is taken. This definition has the important consequence that

$$(x - a) \, P \left( \frac{1}{x - a} \right) = 1$$  \hspace{1cm} (6.224)

since the left side of (6.224) is unity at $x = a$ no matter from which side the limit is taken.

Note that (6.222) says that for any wave number $k$, there are an infinite number of normal modes, one for each value of real $\omega$. This is in contrast to the initial value problem for $E(x, t)$, where only one normal mode was found for each value of $k$ (if negative frequencies are counted, then two normal modes were found for each value of $k$). Note further that the normal modes are not damped, but exist for all time with real frequency $\omega$.

Let us verify that (6.222) is indeed a solution of (6.221). The left side is simplified because one of its terms is of the form $i\delta(u)$, which is zero. Thus, in (6.221),

$$\text{left side} = \eta(v)$$  \hspace{1cm} (6.225)

On the right side of (6.221), the two terms involving principal values cancel each other when integrated over $v$, and we are left with only the term
right side = \eta(v) \quad (6.226)

so that the left and right sides of (6.221) are indeed equal and (6.222) is indeed a normal mode solution. Since (6.221) is a linear equation, \tilde{f}(v) in (6.222) can be multiplied by any constant.

**EXERCISE** Verify (6.225) and (6.226).

What is the electric field associated with this normal mode? Using (6.219), we find

\[
E_0 = \frac{-4\pi e}{ik} \int_{-\infty}^{\infty} dv \tilde{f}_1(v) \quad (6.227)
\]

or

\[
E_0 = \frac{-4\pi e}{ik} \quad (6.228)
\]

so that

\[
E(x,t) = \frac{-4\pi e}{ik} e^{-i\omega t + ikx} \quad (6.229)
\]

is the electric field associated with the normal mode (6.222).

These normal modes are peculiar, both mathematically and physically. Mathematically, we have \(f_1(v = \omega/k) \to \infty\) because of the \(\delta\)-function in (6.222). But it is not consistent to linearize the Vlasov equation with \(f = f_0 + f_1\) and then find \(f_1\) infinite! Physically, (6.222) says that we must have a finite number of particles per unit spatial volume with velocity exactly equal to \(\omega/k\), which is impossible to do. We conclude that the individual Case–Van Kampen modes as given by (6.222) are not physically relevant. What then is the importance of the modes in (6.222)?

The importance of the modes in (6.222) lies in the possibility of creating a physically and mathematically acceptable disturbance by adding up many such modes. Consider a fixed wave number \(k\). Since the basic linearized Vlasov–Poisson system is indeed linear, we may construct a solution by taking any linear combination of the solutions in (6.222). The general solution is

\[
f_1(x,v,t) = e^{ikx} \int_{-\infty}^{\infty} d\omega \ e^{-i\omega t} \tilde{f}_1(v,\omega) c(\omega) \quad (6.230)
\]

where we label the normal modes of (6.222) by their frequency \(\omega\), and \(c(\omega)\) is an arbitrary weighting function. For sufficiently well behaved \(c(\omega)\), the singularities in \(\tilde{f}_1(v,\omega)\) will be smoothed out, and \(f_1(x,v,t)\) will be a mathematically and physically nice function. For a given initial condition \(f_1(x,v,t = 0)\), the function \(c(\omega)\) must be chosen such that (6.230) yields the correct solution at \(t = 0\).

Inserting (6.222) for \(\tilde{f}_1(v)\) into (6.230), we find

\[
f_1(x,v,t) = e^{ikx} \eta(v) P \int_{-\infty}^{\infty} d\omega \frac{e^{-i\omega t} c(\omega)}{v - (\omega/k)} + e^{ikx} k e^{-i\omega t} c(\omega = kv) - k e^{ikx - i\omega t} c(\omega = kv) P \int_{-\infty}^{\infty} \frac{\eta(v')dv'}{v' - v} \quad (6.231)
\]
where we have used \(\delta(v - \omega/k) = k\delta(\omega - kv)\). Consider the middle term in (6.231). This term does not damp away at late times, but rather oscillates in velocity faster and faster with increasing time, as shown in Fig. 6.39. This behavior is due to the free streaming of particles, and would occur for \(f_1(x,v,t)\) even if the charge of the electrons were zero. For example, consider the linearized Vlasov equation (6.216) when the charge is zero:

\[
\partial_t \tilde{f}_1 + ikv\tilde{f}_1 = 0
\]  

(6.232)

where spatial dependence \(e^{ikx}\) is assumed. The solution of (6.232) is

\[
\tilde{f}_1(v,t) = \tilde{f}_1(v,t = 0)e^{-ikvt}
\]  

(6.233)

which becomes more and more pathological with increasing time. Physically, a small number of collisions would wipe out this behavior at late time.

Returning to the general case with a nonzero charge, we can ask: Does the electric field behave more reasonably? Yes it does. From Poisson's equation,

\[
E(x,t) = -\frac{4\pi e}{ik} \int_\infty^\infty dv f_1(v,x,t)
\]  

(6.234)

or

\[
E(x,t) = 4\pi ei e^{ikx} \int_\infty^\infty dv e^{-ikvt}c(\omega = kv)
\]  

(6.235)

where the first and last terms on the right of (6.231) cancel upon integration.

---

**Fig. 6.39** A portion of the distribution function of a Case–Van Kampen mode at two different times.
EXERCISE Verify this.

The right side of (6.235) is in the form of a Fourier transform. It turns out that when $c(\omega)$ is correctly chosen to represent the initial $f_j(x,v,t)$ through (6.230), then (6.235) is exactly equivalent to the expression (6.35) together with (6.34). Thus, the right side of (6.235) would produce transients, as before, together with the correct Landau damped normal modes. Thus, there is complete agreement between the normal mode picture for $E(x,t)$ of Sections 6.4 and 6.5, and the normal mode picture for $f_j(x,v,t)$ of the present section. The latter is somewhat more complete, since $f_j(x,v,t)$ determines $E(x,t)$ and therefore determines its own future at all times, while $E(x,t)$ could be produced by many different functions $f_j(x,v,t)$ and therefore does not determine its own future at all times. In practice, either approach may be used because $E(x,t)$ does pick out the slowly Landau damped normal modes of the system at late times, after the transients have died away.

This brings us to the end of our discussion of the Vlasov equation. We recall that the Vlasov equation is obtained as an approximate theory from the Klimontovich and Liouville approaches of Chapters 3 to 5 by neglecting the physics of collisions. In the next two chapters, we take moments of the Vlasov equation to obtain even simpler and more approximate theories of a plasma; these are the fluid theory and magnetohydrodynamics.

REFERENCES

**PROBLEMS**

6.1 Resistive vs. Reactive Instabilities

The type of instability found in (6.52) when \( d_{\omega}g(u)|_{\omega=\omega_{k}} > 0 \) is often called a "resistive" instability; these are instabilities to which (6.42) and (6.43) apply. Show why (6.42) and (6.43) do not apply to the dielectric function \( \varepsilon(\omega) = 1 + \omega_{0}^{2}/\omega^{2} \), which yields a "reactive" instability.

6.2 Ion-Acoustic Waves

The dispersion relation (6.21) has a branch describing ion-acoustic waves as well as one describing Langmuir waves. We consider \( g(u) \) given by two Maxwellians as in (6.24), with \( T_{i} << T_{e} \), and look for a wave with phase speed such that

\[
\upsilon_{i} << \omega/k << \upsilon_{e}
\]

For the ion contribution, expand the denominator in (6.21) as in (6.26). For the electron contribution, approximate the integral by ignoring \( \omega/k << \upsilon_{e} \) in the denominator. Then solve the dispersion relation \( \varepsilon(k, \omega) = 0 \) to find \( \omega = \omega(k) \) for ion-acoustic waves.

6.3 Electrostatic Waves

The dispersion relation (6.21) for electrostatic waves must be solved using the Landau contour of Section 6.4; alternatively, the integral can be evaluated for \( \omega_{i} > 0 \) and the result analytically continued to \( \omega_{i} < 0 \). Evaluate (6.21) and find the normal modes \( \omega(k) \) for the following distribution functions \( g(u) \).

(a) Cold plasma, \( g(u) = \delta(u) \).
(b) Cold beam, \( g(u) = \delta(u - u_{0}) \).
(c) Square distribution, \( g(u) = (2c)^{-1} \) for \( |u| < c \), \( g(u) = 0 \) for \( |u| > c \); \( c \) is a real positive constant.
(d) Cauchy distribution, \( g(u) = (c/\pi)(u^{2} + c^{2})^{-1} \). (Why can there never be a true Cauchy distribution?)

6.4 Ion-Acoustic Wave Energy

Apply the wave energy formula (6.72) to the ion-acoustic dielectric function derived in Problem 6.2. Is most of the energy in electric field energy or in particle energy? Explain physically and in detail why this is so (see discussion in Chapter 7).

6.5 Two Drifting Cauchy Distributions

Consider a Vlasov equilibrium consisting of infinitely massive ions and two counterstreaming Cauchy distributions (see Problem 6.3) such that
126 \text{ Vlasov Equation}
\[
g(u) = \frac{\Delta}{2\pi} \left[ \frac{1}{(u - a)^2 + \Delta^2} + \frac{1}{(u + a)^2 + \Delta^2} \right]
\]
(a) Sketch $g(u)$.
(b) Apply Gardner’s theorem to show that stability is guaranteed for $a < \Delta / \sqrt{3}$.
(c) Apply the Penrose criterion to show that this equilibrium is stable for $a < \Delta$, and unstable for $a > \Delta$.

6.6 \text{ Isotropic Stability}
(a) Consider a plasma with infinitely massive ions and an electron distribution function that is the surface of a sphere in three-dimensional velocity space,
\[
f_e(v) = C \delta(v - v_0) = C \delta[(v_x^2 + v_y^2 + v_z^2)^{1/2} - v_0]
\]
Calculate $g(u)$, sketch it, and use Gardner’s theorem to show that this distribution is stable to electrostatic perturbations.
(b) Consider any isotropic distribution function
\[
f_e(v) = f_s(v)
\]
Use Gardner’s theorem to show that such a distribution is stable to electrostatic perturbations.
7.1 INTRODUCTION

There are many phenomena in plasma physics that can be studied by thinking of the plasma as two interpenetrating fluids, an electron fluid and an ion fluid. In this approach, it is not necessary to consider the fact that each species consists of particles with different velocities. The advantage of this approach is its simplicity; it leads to equations in three spatial dimensions and time rather than in the seven-dimensional phase space of Vlasov theory (Chapter 6). The disadvantage of this approach is that it misses velocity-dependent effects such as Landau damping.

In this section, we introduce the fluid equations heuristically, for the benefit of those readers who have not yet studied Chapter 6 on Vlasov theory. In the next section, we present a more rigorous derivation of the fluid equations from the Vlasov equation.

The first equation of fluid theory is the continuity equation, which expresses the fact that the fluid is not being created or destroyed, so that the only way that the fluid density \( n_s(x,t) \) of fluid species \( s \) can change at a point \( x = (x,y,z) \) is by having a net amount of fluid enter or leave a small spatial volume including that point. The density \( n_s \) is the number of particles of species \( s \) per unit volume. To every element of fluid there corresponds a velocity vector \( V_s(x,t) \) that gives the velocity of the fluid element at the point \( x \) at time \( t \). Mathematically, the continuity equation for fluid species \( s \) is

\[
\partial_t n_s(x,t) + \nabla \cdot (n_s V_s) = 0
\]  

(7.1)

where \( \nabla = (\partial_x, \partial_y, \partial_z) \) is the usual gradient operator in three-dimensional configu-
Fluid Equations

A derivation of the fluid continuity equation can be found in most undergraduate mechanics books (see, for example, Ref. [1]).

The second equation of fluid theory is the force equation, which is simply Newton's second law of motion for a fluid. This can be written for fluid species $s$ as

$$n_s m_s \dot{V}_s(x,t) = F_s(x,t) \quad (7.2)$$

where $F_s(x,t)$ is the force per unit volume acting on the fluid element at position $x$ at time $t$. The time derivative on the left of Newton's law refers to the fluid element as an entity and therefore must be taken along the orbit of the fluid element. Thus,

$$\dot{V}_s(x,t) = \frac{dx}{dt} \bigg|_{\text{orbit}} \cdot \nabla V_s$$

$$= \partial_i V_s + (V_s \cdot \nabla) V_s \quad (7.3)$$

On the right side of (7.2) are all of the forces that act on a fluid element. One such force is the pressure gradient force. A fluid of charged particles has a pressure $P_s(x,t) = n_s(x,t)T_s(x,t)$ and an associated force per unit volume $-\nabla P_s$. Another force is the Lorentz force per unit volume, $q_s n_s(x,t)E(x,t) + \left( q_s/c \right) n_s(x,t)V_s(x,t) \times B(x,t)$. With these forces, Eq. (7.2) becomes

$$n_s m_s \frac{\partial}{\partial t} V_s + n_s m_s V_s \cdot \nabla V_s = -\nabla P_s + q_s n_s E + \frac{q_s}{c} n_s V_s \times B \quad (7.4)$$

or

$$\frac{\partial}{\partial t} V_s + V_s \cdot \nabla V_s = \frac{-1}{n_s m_s} \nabla P_s + \frac{q_s}{m_s} E + \frac{q_s}{m_s c} V_s \times B \quad (7.5)$$

which can be thought of as the force equation per particle. The fields $E(x,t)$ and $B(x,t)$ are the macroscopic fields (those which would be measured by a probe), as discussed in Chapter 3.

With the given fluid quantities, the total charge density $\rho$ is defined by

$$\rho(x,t) = \sum_s q_s n_s(x,t) \quad (7.6)$$

while the total current density $J$ is defined by

$$J(x,t) = \sum_s q_s n_s(x,t) V_s(x,t) \quad (7.7)$$

When combined with Maxwell's equations

$$\nabla \cdot E(x,t) = 4\pi \rho \quad (7.8)$$

$$\nabla \cdot B(x,t) = 0 \quad (7.9)$$

$$\nabla \times E(x,t) = -\frac{1}{c} \partial_t B \quad (7.10)$$

$$\nabla \times B(x,t) = \frac{4\pi}{c} J + \frac{1}{c} \partial_t E \quad (7.11)$$

the fluid equations provide a complete, but approximate, description of plasma physics. A more careful development of the fluid equations from the Vlasov
equation is provided in the next section. The reader who has not yet studied the Vlasov equation (Chapter 6) can proceed directly to Section 7.3.

7.2 DERIVATION OF THE FLUID EQUATIONS FROM THE VLASOV EQUATION

Except for the neglect of collisions, the Vlasov equation (Chapter 6) is an exact description of a plasma. By taking velocity moments of the Vlasov equation in seven-dimensional \((x,v,t)\) space, an infinite hierarchy of equations in four-dimensional \((x,t)\) space can be derived. When an appropriate truncation of this infinite hierarchy is carried out, the standard two-fluid theory of plasma physics is obtained. This procedure is reminiscent of the truncation of the BBGKY hierarchy in Chapter 4 that led to the plasma kinetic equation and thence to the Vlasov equation.

The Vlasov equation (6.5) is

\[
\partial_t f_s(x,v,t) + v \cdot \nabla_x f_s + \frac{q_s}{m_s} \left( E + \frac{v}{c} \times B \right) \cdot \nabla_v f_s = 0 \tag{6.5}
\]

We use the normalization

\[
n_s(x,t) = \int dv f_s(x,v,t) \tag{7.12}
\]

and note that the fluid velocity \(V_s\) is

\[
V_s(x,t) = \frac{1}{n_s} \int dv v f_s(x,v,t) \tag{7.13}
\]

The first fluid equation (the continuity equation) is obtained by integrating (6.5) over all velocity space (i.e., we first multiply by “unity”). The first term yields \(\partial_t n_s(x,t)\). The second term is

\[
\int dv v \cdot \nabla_x f_s = \nabla_x \cdot \int dv v f_s = \nabla_x \cdot (n_s V_s) \tag{7.14}
\]

The third and fourth terms vanish upon performing the velocity integration.

**EXERCISE**  Show the above.

The result is the exact continuity equation

\[
\partial_t n_s(x,t) + \nabla_x \cdot (n_s V_s) = 0 \tag{7.15}
\]

which agrees with (7.1). (Except in this section, \(\nabla_x\) is denoted by \(\nabla\) in this chapter.)

The force equation is obtained by multiplying (6.5) by \(v\) and integrating over all velocity space. This yields

\[
\frac{\partial}{\partial t} \int dv v f_s + \int dv vv \cdot \nabla_x f_s + \frac{q_s}{m_s} \int dv v \left[ \left( E + \frac{1}{c} v \times B \right) \cdot \nabla_v f_s \right] = 0 \tag{7.16}
\]
Fluid Equations

In term (1), we have $\partial_t(n_s V_s)$ by (7.13). In (2), we perform the manipulation $v v \cdot \nabla_x f_s = v \cdot \nabla_x (v f_s) = \nabla_x \cdot (v v f_s)$. Since $f_s(x,v,t)$ is a probability distribution, the ensemble average of any quantity is

$$\langle g \rangle = \frac{\int dv g f_s}{\int dv f_s} = \frac{1}{n_s} \int dv g f_s$$  \hspace{1cm} (7.17)

Thus, term (2) is

$$\nabla_x \cdot \int dv v v f_s = \nabla_x \cdot (n_s \langle v v \rangle)$$  \hspace{1cm} (7.18)

Term (3) is easily evaluated by an integration by parts, yielding $-(q_s/m_s) E n_s$.

**EXERCISE** Verify this result for at least one component of the combination $v E \cdot \nabla v$.

In term (4), it is useful to move $\nabla_v$ to the left, obtaining $\nabla_v \cdot [(v \times B) f_s]$; an integration by parts then yields

$$\nabla_v \cdot [(v \times B) f_s] = -\frac{q_s}{m_e} \int dv (v \times B) f_s = -\frac{q_s}{m_e} n_s (V_s \times B)$$  \hspace{1cm} (7.19)

where we have evaluated each component in (7.19) using (7.13). Combining all terms, (7.16) becomes

$$\partial_t(n_s V_s) + \nabla \cdot (n_s \langle v v \rangle) = \frac{q_s}{m_e} n_s \left( E + \frac{1}{c} V_s \times B \right)$$  \hspace{1cm} (7.20)

which is the fluid force equation for species $s$. Multiplying through by the mass $m_s$, we see that each term has units of (force/volume). Equation (7.20) is also called the momentum equation, since it determines the time rate of change of momentum per unit volume.

Note that the continuity equation (7.15) for $n_s$ involves the function $V_s$, and the force equation (7.20) for $V_s$ involves the function $\langle v v \rangle$. It is clear that every equation for $n$ factors of $v$ will involve a term with $n + 1$ factors of $v$. Thus, to obtain a complete description of a plasma, we need an infinite number of moment equations as derived from the Vlasov equation. This is equivalent to replacing the seven-dimensional Vlasov equation by an infinite number of four-dimensional fluid equations. In practice, we seek to truncate this series of equations by using a physical argument to evaluate the term with $n + 1$ factors of $v$, rather than using the fluid equation for that term. For example, we shall use physical arguments to evaluate the $\langle v v \rangle$ term in (7.20), so that the force equation (7.20), the continuity equation (7.15), and Maxwell’s equations become a complete description of the plasma. In detailed descriptions of plasmas found, for example, in magnetic confinement devices and in the solar wind, the fluid equation for $\langle v v \rangle$ is used and physical arguments are used to evaluate terms with three components of velocity [2]. The equation for the time derivative of $\langle v v \rangle$ is known as the energy equation.

There are various circumstances where it is easy to evaluate $\langle v v \rangle$. For example, suppose the species is cold, so that all particles have the same macroscopic velocity $V_s$. Then $f_s(x,v,t) = n_s(x,t)\delta(v - V_s)$; thus
\[ \langle v \cdot v \rangle = \frac{1}{n_s} \int dv \, n_s(v) \delta(v - V_s) = V_s V_s \]  \hspace{1cm} (7.21)

**EXERCISE** Verify (7.21), recalling that \( \delta(v - V_s) = \delta(v_x - V_{sx}) \delta(v_y - V_{sy}) \delta(v_z - V_{sz}) \).

Another case is where the distribution function \( f_s(x,v,t) \) is isotropic at each point in space. Then with

\[ \langle v \cdot v \rangle = \begin{pmatrix} u_x v_x & u_y v_y & u_z v_z \\ u_x v_x & u_y v_y & u_z v_z \\ u_x v_x & u_y v_y & u_z v_z \end{pmatrix} \]  \hspace{1cm} (7.22)

we have \( V_s = 0 \), and upon taking the average, all of the off-diagonal terms in (7.22) vanish.

**EXERCISE** Prove this case.

The diagonal terms are \( \langle u_x^2 \rangle = \langle u_y^2 \rangle = \langle u_z^2 \rangle = v_s^2 \) where \( v_s(x) \) is the thermal speed. Equation (7.22) becomes

\[ \langle v \cdot v \rangle = v_s^2(x) \bar{\mathbf{I}} \]  \hspace{1cm} (7.23)

where \( \bar{\mathbf{I}} \) is the unit tensor, and we take into account the possibility that the temperature \( (T_s \equiv m_s v_s^2) \) is spatially dependent.

The second term in (7.20) than takes the form

\[ \nabla \cdot (n_s \langle v \cdot v \rangle) = \nabla \cdot (n_s v_s^2 \bar{\mathbf{I}}) = \nabla(n_s v_s^2) = \nabla P_s / m_s \]  \hspace{1cm} (7.24)

where the pressure \( P_s \equiv n_s m_s v_s^2 = n_s T_s \).

More generally, we might have a distribution that has a net velocity \( \mathbf{V}_s \) in a certain direction, and has an isotropic velocity distribution in the frame moving with velocity \( \mathbf{V}_s \); therefore \( \langle (v_x - V_{sx})^2 \rangle = \langle (v_y - V_{sy})^2 \rangle = \langle (v_z - V_{sz})^2 \rangle = v_s^2 = P_s / m_s n_s \). Then

\[ \langle v \cdot v \rangle = V_s V_s + \frac{P_s}{m_s n_s} \bar{\mathbf{I}} \]  \hspace{1cm} (7.25)

and

\[ \nabla \cdot (n_s \langle v \cdot v \rangle) = \nabla \cdot (n_s \mathbf{V}_s \mathbf{V}_s) + \frac{1}{m_s} \nabla P_s \]

\[ = (\nabla \cdot \mathbf{V}_s)(n_s \mathbf{V}_s) + (\mathbf{V}_s \cdot \nabla)(n_s \mathbf{V}_s) + \frac{1}{m_s} \nabla P_s \]  \hspace{1cm} (7.26)

**EXERCISE** By writing out components, or by any other method, justify the manipulations in (7.26).

The force equation (7.20) becomes, multiplying by \( m_s \),

\[ \partial_t (m_s n_s \mathbf{V}_s) + (\nabla \cdot \mathbf{V}_s)(m_s n_s \mathbf{V}_s) + (\mathbf{V}_s \cdot \nabla)(m_s n_s \mathbf{V}_s) \]

\[ = -\nabla P_s + q_s n_s \left( \mathbf{E} + \frac{1}{c} \mathbf{V}_s \times \mathbf{B} \right) \]  \hspace{1cm} (7.27)
Fluid Equations

Equation (7.27) can be simplified by subtracting the continuity equation (7.15), multiplied by \( V_s \), from the left side. We find

\[
m_s n_s \partial_s V_s + m_s n_s (V_s \cdot \nabla) V_s = -\nabla P_s + q_s n_s \left( E + \frac{1}{c} V_s \times B \right)
\]  

(7.28)

in agreement with (7.5).

When combined with Maxwell's equations, and when some means is found for describing the pressure \( P_s \), Eqs. (7.15) and (7.28) provide a complete description of fluid plasma behavior. We shall find several different means for describing the pressure. For variations in one direction only, the pressure is \( P_s = n_s T_s = n_s m_s \langle v^2 \rangle \) where we evaluate \( \langle v^2 \rangle \) along the direction of variation. If we are dealing with a motion, a wave for example, which is slowly varying compared to the equilibration time of species \( s \), we might have isothermal behavior so

\[
\nabla P_s = \nabla (n_s T_s) = T_s \nabla n_s
\]  

(7.29)

On the other hand, a rapidly varying compression may involve adiabatic motion, so

\[
\nabla P_s = \nabla (n_s T_s) = n_s T_s \nabla n_s = \gamma_s T_s \nabla n_s
\]  

(7.30)

where \( \gamma_s = (2 + D)/D \) is the so-called "ratio of specific heats." Here, \( D \) is the number of dimensions that share in the increased temperature, and it is assumed that the motion in (7.30) involves only small departures of the density and temperature from their unperturbed values \( n_s, T_s \). In succeeding sections on wave motions in fluid plasma, we shall apply these ideas.

**EXERCISE** Verify (7.30) using the basic ideas of adiabatic compressions.

### 7.3 Langmuir Waves

Now that we have developed a complete description of a plasma, in the form of the two-fluid equations, what can we do with it? The first thing we can do is to study the various kinds of waves that can propagate through a plasma. Waves are very important. They propagate energy from one part of a plasma to another. They send information out of the plasma that enables an external observer to know what is occurring inside. They can become unstable, growing as they propagate, to such large amplitudes that they disrupt the confinement of a plasma.

Our first example of a wave is a very simple one, the electron plasma wave, or Langmuir wave (also called a space-charge wave). Suppose the ions are infinitely massive, so that they do not contribute to the motion, but have a fixed particle density \( n_0 \) and a fixed charge density \( en_0 \). Then we need only three equations to describe the electron motion: the electron continuity equation, the electron force equation, and Poisson's equation. These are (in one dimension, with \( B_0 = 0 \))

\[
\frac{\partial}{\partial t} n_e + \partial_x (n_e V_e) = 0
\]  

(7.31)

\[
m_e (\partial_t V_e + V_e \partial_x V_e) = -\partial_x P_e - en_e E
\]  

(7.32)
and

\[ \partial_t E = 4\pi e(n_0 - n_e) \quad (7.33) \]

We seek solutions to (7.31) to (7.33) in the form of small amplitude waves, where the electric field has a sinusoidal spatial variation. In order to look for such small amplitude waves, we first linearize (7.31) to (7.33). With

\[ n_e = n_0 + n_1 \quad (7.34) \]
\[ E = E_1 \quad (7.35) \]

and

\[ V_e = v_1 \quad (7.36) \]

we first neglect the pressure \( P_e \), assuming that the electrons are cold. Then the only zeroth order contribution from (7.31) to (7.33) is

\[ \partial_t n_0 = 0 \quad (7.37) \]

which is trivially satisfied. The first order terms are

\[ \partial_t n_1 + n_0 \partial_x v_1 = 0 \quad (7.38) \]
\[ m_e n_0 \partial_x v_1 = -en_0 E_1 \quad (7.39) \]

and

\[ \partial_x E_1 = -4\pi e n_1 \quad (7.40) \]

These equations are now linear, and we may look for wave solutions in which each variable has the form \( \cos (kx - \omega t + \theta) \),

\[ E_1(x,t) = \tilde{E}_1 \cos (kx - \omega t) \quad (7.41) \]
\[ n_1(x,t) = \tilde{n}_1 \cos (kx - \omega t + \theta_n) \quad (7.42) \]

and

\[ v_1(x,t) = \tilde{v}_1 \cos (kx - \omega t + \theta_v) \quad (7.43) \]

where \( \tilde{E}_1, \tilde{n}_1, \) and \( \tilde{v}_1 \) are real constants and \( \theta_n, \theta_v \) are possible phase shifts. It turns out that it is very awkward to use \( \sin \)'s and \( \cos \)'s, and it is very convenient to use solutions that vary as \( \exp (-i\omega t + ikx) \). We may do this by noting that if (7.41) to (7.43) is a solution of the linearized equations (7.38) to (7.40), then the expression obtained by giving each of (7.41) to (7.43) a phase shift of \( \pi/2 \) will also be a solution, where \( \sin \) replaces \( \cos \) in (7.41) to (7.43). Any linear combination of these two sets of solutions will also be a solution; in particular, \([\cos \text{ solution}] + i[\sin \text{ solution}]\) is a solution, of the form

\[ E_1(x,t) = \tilde{E}_1 \exp (-i\omega t + ikx) \quad (7.44) \]
\[ n_1(x,t) = \tilde{n}_1 \exp (i\theta_n) \exp (-i\omega t + ikx) \quad (7.45) \]

and

\[ v_1(x,t) = \tilde{v}_1 \exp (i\theta_v) \exp (-i\omega t + ikx) \quad (7.46) \]

If we next absorb the phase factors \( \exp (i\theta_n) \) and \( \exp (i\theta_v) \) into new complex constants \( \tilde{n}_1 = n_1 \exp (i\theta_n), \tilde{v}_1 = v_1 \exp (i\theta_v) \), we have
\[ E_1(x,t) = \tilde{E}_1 \exp(-i\omega t + ikx) \]  
(7.47)

\[ n_1(x,t) = \tilde{n}_1 \exp(-i\omega t + ikx) \]  
(7.48)

and

\[ v_1(x,t) = \tilde{v}_1 \exp(-i\omega t + ikx) \]  
(7.49)

After we have obtained the solutions (7.47) to (7.49), we can add them to their complex conjugate to obtain the physically relevant real solutions, if desired.

**EXERCISE** Why is the complex conjugate of (7.47) to (7.49) also a solution?

Inserting the assumed wave solution (7.47) to (7.49) into the linearized equations (7.38) to (7.40), one obtains

\[-i\omega \tilde{n}_1 + ikn_0 \tilde{v}_1 = 0 \]  
(7.50)

\[-i\omega \mu \tilde{n}_0 \tilde{v}_1 = -en_0 \tilde{E}_1 \]  
(7.51)

and

\[ ik \tilde{E}_1 = -4\pi en_0 \]  
(7.52)

where we have divided each side by \( \exp(-i\omega t + ikx) \). Solving (7.50) for \( \tilde{v}_1 \) in terms of \( \tilde{n}_1 \), and solving (7.52) for \( \tilde{n}_1 \) in terms of \( \tilde{E}_1 \), and inserting in (7.51), we find

\[ \frac{\omega^2 m_e}{4\pi n_0 e^2} \tilde{E}_1 = \tilde{E}_1 \]  
(7.53)

Upon dividing by the constant \( \tilde{E}_1 \), we see that

\[ \omega^2 = \frac{4\pi n_0 e^2}{m_e} = \omega_e^2 \]  
(7.54)

or

\[ \omega = \pm \omega_e \]  
(7.55)

for our cold plasma oscillations; thus the wave frequency is just our old friend the electron plasma frequency.

**EXERCISE** If we had kept the ion component with mass \( m_i \), can you guess what the wave frequency would be?

Thus, we have shown that any expression of the form (7.44) to (7.46) is a solution of (7.38) to (7.40), provided the frequency is given by (7.55). Note that this is true for arbitrary wave number \( k \).

**EXERCISE** Using (7.50) to (7.52), determine the phase shifts between \( E_1, n_1, \) and \( v_1 \). Choosing a value of \( k \), add (7.47) to (7.49) to its complex conjugate to obtain real solutions, and sketch these solutions with their appropriate phase shifts.

The expression (7.55) for \( \omega \) is called a dispersion relation, because it is supposed to represent the relation between frequency \( \omega \) and wave number \( k \). In this case the dispersion relation is trivial, because it does not depend on \( k \). The group velocity
\[ \nu_g = \frac{\partial \omega}{\partial k} = 0 \]  

(7.56)

does not depend on wave number \( k \), so these waves are dispersionless. An initial wave packet will not propagate, but merely oscillates forever at frequency \( \omega = \omega_e \).

Thus, the physics of these waves is as simple as the physics of the oscillating slabs used to derive the plasma frequency in Chapter 1.

It is always useful to sketch dispersion relations. In this case, the sketch of (7.55) is simple, consisting of two straight lines at \( \omega = \pm \omega_e \), as shown in Fig. 7.1.

The most serious assumption in our derivation of the cold plasma waves is the neglect of the pressure term in (7.32). Let us repeat the derivation, including the pressure \( P_e \). We have \( \nabla P_e = \nabla(n_e T_e) = \nabla((n_o + n_i)(T_o + T_i)) = n_o \nabla T_e + T_o \nabla n_i \), keeping only first order terms. Now in order to relate the first order temperature change \( T_j \) in the wave to the first order density change \( n_i \), we must go outside the fluid theory. We consider long wavelength waves, such that a typical electron travels only a fraction of a wavelength \( \lambda \) in one wave period; then the compression of the wave will be an adiabatic one. Thus, the assumption \( v_e \omega^{-1} \ll \lambda \), or

\[ \omega/k \gg v_e \]  

(7.57)

leads us to consider adiabatic compressions. If we further assume that the collision frequency is small,

\[ v_e \ll \omega \]  

(7.58)

then the change in temperature during the compression along the direction of wave propagation will not be transmitted to the other two directions. We conclude that our compression is a one-dimensional adiabatic compression, which means that

\[ \nabla P_e = n_o \nabla T_e + T_o \nabla n_i = 3T_o \nabla n_i \]  

(7.59)

by the expression below (7.30).

With the expression (7.59) for \( \nabla P_e \), our previous derivation goes through with the addition of one term; thus (7.50) to (7.52) are replaced by

![Fig. 7.1 Dispersion relation for electron plasma waves when the pressure is ignored.](image)
Fluid Equations

Fig. 7.2  Langmuir wave dispersion diagram.

\[-i \omega_1 \ddot{\bar{n}}_1 + i k \ddot{\bar{n}}_1 \ddot{v}_1 = 0 \tag{7.60}\]
\[-i \omega m_0 \ddot{\bar{n}}_1 = -en_0 \dddot{E}_1 - ik 3T_0 \dddot{\bar{n}}_1 \tag{7.61}\]
\[i k \dddot{\bar{n}}_1 = -4\pi e \dddot{\bar{n}}_1 \tag{7.62}\]

Solving (7.60) for \(\ddot{v}_1\), solving (7.62) for \(\dddot{\bar{n}}_1\), and inserting in (7.61), one finds

\[(\omega^2 - \omega_e^2 - 3k^2T_0/m_e)\dddot{E}_1 = 0 \tag{7.63}\]
or

\[
\omega^2 = \omega_e^2 + 3k^2T_0/m_e = \omega_e^2 + 3k^2v_e^2
\]

which is the famous Langmuir wave dispersion relation (see Eq. 6.28).

Since we have used the assumption (7.57), the dispersion relation (7.64) has a limited range of validity, restricted to

\[v_e \ll \frac{\omega}{k} \approx \frac{\omega_e}{k} \tag{7.65}\]
or

\[k \lambda_e \ll 1 \tag{7.66}\]

Thus, another useful form of (7.64) is

\[
\omega = \pm (\omega_e^2 + 3k^2v_e^2)^{1/2} \approx \pm \omega_e \left(1 + \frac{3}{2}k^2\lambda_e^2\right) \tag{7.67}\]

A graph of the dispersion relation (7.67) is shown in Fig. 7.2. The Langmuir wave is seen to have dispersion, since the group velocity is

\[V_g \equiv \frac{d\omega}{dk} = 3(k\lambda_e)v_e \tag{7.68}\]

and this depends on wave number.

**EXERCISE** Returning to (7.60) to (7.62), find the density perturbation and velocity perturbation associated with the wave. Show that for \(k \to 0\) we regain the cold plasma wave, while for \(k > 0\) the pressure acts as an additional restoring force which gives the wave a higher frequency.

### 7.4 DIelectric FUNCTION

It is often useful to draw an analogy between a plasma and a dielectric medium. Recall that in ordinary dielectric theory, we are able to replace Poisson's equation for charges in a vacuum,
\[ \nabla \cdot \mathbf{E} = 4\pi \rho \]  
(7.69)

by

\[ \nabla \cdot \mathbf{D} = 0 \]  
(7.70)

where

\[ \mathbf{D} = \varepsilon \cdot \mathbf{E} \]  
(7.71)

Here \( \varepsilon \) is the dielectric tensor, the properties of the medium have been incorporated into the displacement \( \mathbf{D} \), and we assume there are no additional free charges. This same operation can of course be performed for a plasma as well as for a dielectric medium. In one dimension, and assuming plane wave fields, Eq. (7.69) is

\[ ikE = 4\pi \rho \]  
(7.72)

so that if we can write \( \rho \) in terms of \( E \) it will be easy to identify the dielectric function:

\[ ik \left( E - \frac{4\pi \rho}{ik} \right) \equiv ikeE = 0 \]  
(7.73)

For cold plasma waves this has been done in (7.50) to (7.52), which are easily written in the form

\[ ik \left( 1 - \frac{\omega_e^2}{\omega^2} \right) E = 0 \]  
(7.74)

so that the dielectric function is

\[ \varepsilon(\omega) = 1 - \frac{\omega_e^2}{\omega^2} \]  
(7.75)

and we notice that the dispersion relation (7.55) is precisely equivalent to equating \( \varepsilon(\omega) \) to zero,

\[ \varepsilon(\omega) = 0 \Rightarrow \omega = \pm \omega_e \]  
(7.76)

Thus, we see that the normal modes of a plasma are obtained from the zeros of the dielectric function (see Chapter 6).

**EXERCISE** Verify (7.74).

In a similar fashion, because (7.60) to (7.62) for Langmuir waves can be written in the form

\[ ik \left[ 1 - \frac{\omega_e^2}{\omega^2 - 3k^2v_e^2} \right] E = 0 \]  
(7.77)

we identify the dielectric function

\[ \varepsilon(\omega, k) = 1 - \frac{\omega_e^2}{\omega^2 - 3k^2v_e^2} \]  
(7.78)

the zeros of which yield the normal modes (7.67):

\[ \varepsilon(\omega, k) = 0 \Rightarrow \omega(k) \]  
(7.79)

\[ \omega(k) = \omega_e(1 + 3k^2\lambda_e^2)^{1/2} \]  
(7.80)

The dielectric function has been studied in more detail in Chapter 6.
7.5 ION PLASMA WAVES

In Section 7.3 we studied high frequency electron plasma oscillations, with frequency $\omega$ near the electron plasma frequency $\omega_e$. For these waves, the ion motion is negligible and irrelevant. Here, we consider low frequency waves, $\omega \leq \omega_i$, where the ion motion dominates the wave physics. (In an unmagnetized plasma, the words “low frequency” refer to $\omega \leq \omega_i$ while “high frequency” refers to $\omega \geq \omega_i$. In a magnetized plasma, we often have the ordering $\Omega_i \ll \omega_i \ll \omega_e \ll |\Omega_e|$. (Why?) Then “low frequency” means $\omega \leq \Omega_i$, and other frequencies are called low or high depending on what they are being compared to.)

To include both electron and ion physics, we need five fluid equations: electron and ion continuity, electron and ion force, and Poisson’s equation. These are, from (7.1) and (7.5),

$$\frac{\partial}{\partial t} n_e + \nabla \cdot (n_e V_e) = 0$$  \quad (7.81)

$$m_e n_e \frac{\partial}{\partial t} V_e + m_e n_e V_e \nabla \cdot V_e = -\nabla P_e - \epsilon n_e E$$  \quad (7.82)

$$\frac{\partial}{\partial t} n_i + \nabla \cdot (n_i V_i) = 0$$  \quad (7.83)

$$m_i n_i \frac{\partial}{\partial t} V_i + m_i n_i V_i \nabla \cdot V_i = -\nabla P_i + \epsilon n_i E$$  \quad (7.84)

and

$$\frac{\partial}{\partial t} E = 4\pi e(n_i - n_e)$$  \quad (7.85)

This set of equations is not as bad as it looks. First, because we intend to linearize, all $V \nabla \cdot V$ terms disappear. Second, all pressure terms can be written $\nabla \cdot P_{\text{ei}} = \gamma_{\text{ei}} T_{\text{ei}} \nabla \cdot n_{\text{ei}}$, where temporarily we do not specify the coefficients $\gamma_{\text{ei}}$, $T_{\text{ei}}$, and $n_{\text{ei}}$ are the unperturbed electron and ion temperatures. Then linearizing (7.81) to (7.85) with $n_e = n_0 + n_{e1}$, and all other quantities first order, we obtain

$$\frac{\partial}{\partial t} n_{e1} + n_0 \frac{\partial}{\partial x} V_e = 0$$  \quad (7.86)

$$m_e n_0 \frac{\partial}{\partial t} V_e = -\gamma_e T_e \frac{\partial}{\partial x} n_{e1} - \epsilon n_0 E$$  \quad (7.87)

$$\frac{\partial}{\partial t} n_{i1} + n_0 \frac{\partial}{\partial x} V_i = 0$$  \quad (7.88)

$$m_i n_0 \frac{\partial}{\partial t} V_i = -\gamma_i T_i \frac{\partial}{\partial x} n_{i1} + \epsilon n_0 E$$  \quad (7.89)

and

$$\frac{\partial}{\partial t} E = 4\pi e(n_{i1} - n_{e1})$$  \quad (7.90)

Before solving (7.86) to (7.90), let us guess the properties of the wave we are looking for. The ions will have a sinusoidal density perturbation as shown in Fig. 7.3. Since the frequency is very low, the electrons see an almost static ion density perturbation, and they will try to obtain the same density in order to prevent huge electric fields. However, since the electrons are flying about very fast, the attempt
to exactly cancel the ion charge distribution will not totally succeed; rather, the
electrons try to smear themselves out more smoothly. Thus, the electron density
perturbation is slightly smaller than the ion density perturbation, and the resulting
density difference produces the electric field of the waves.

**EXERCISE** Draw the electric field produced by the densities in Fig. 7.3.

We have seen the tendency for this cancellation of electron and ion charge
before, in Problem 1.4, “Plasma in a gravitational field.” This important property
is called *quasineutrality*, and it is found in almost all low frequency plasma
behavior.

This discussion encourages us to look for a solution of (7.86) to (7.90) with
\( n_{el} \approx n_{e1} \). We therefore ignore Poisson’s equation; and we find from (7.86) and
(7.88) that we must have \( \dot{V}_e \approx V_i \). We eliminate the electric field by adding (7.87)
and (7.89) to obtain

\[
(m_e + m_i) \frac{\partial V_e}{\partial t} = - (\gamma_e T_e + \gamma_i T_i) \frac{\partial n_{el}}{\partial x}
\]

(7.91)

Next, we eliminate the velocity \( V_e \) by taking the time derivative of (7.86) and
inserting the result in the spatial derivative of (7.91), to obtain

\[
(m_e + m_i) \frac{\partial^2 n_{el}}{\partial t^2} = (\gamma_e T_e + \gamma_i T_i) \frac{\partial^2 n_{el}}{\partial x^2}
\]

(7.92)

or, neglecting \( m_e \) compared to \( m_i \),

\[
\frac{\partial^2 n_{el}}{\partial t^2} = c_s^2 \frac{\partial^2 n_{el}}{\partial x^2}
\]

(7.93)

where we have defined the sound speed

\[
c_s \equiv \left( \gamma_e T_e + \gamma_i T_i \right) / m_i
\]

(7.94)

Assuming a plane wave solution of the form \( \exp (-i\omega t + ikx) \), (7.93) yields the
**ion-acoustic dispersion relation**

\[
\omega^2 = k^2 c_s^2
\]

(7.95)

The name ion-acoustic arises from the similarity between the dispersion relation
(7.95) and the equivalent relation for sound waves traveling through a gas.

It is difficult to determine the regime of validity of (7.95) from the foregoing
discussion. We do know, however, that we have neglected the difference \( n_{el} - n_{e1} \), which by Poisson’s equation is proportional to \( \partial_x E \sim k E \). We thus expect
that (7.95) is limited to small \( k \); we shall see in a moment that this is so.

What shall we take for \( \gamma_e, \gamma_i \)? In practice, this depends on the region of density,
temperature, and wave number in which we are working. It may be the case that
the ion motions are adiabatic in one dimension, so \( \gamma_i = 3 \). It may also be that
collisions are important enough to redistribute the wave compressional energy
in three dimensions, so that \( \gamma_i = (D + 2)/D = 5/3 \) for adiabatic compressions
in three dimensions. As for the electrons, it is the case that a typical electron travels
many wavelengths in one wave period; that is, the distance traveled in one period 
v/\omega \sim v/ke >> k^{-1}, since
\[ \frac{v_e}{c_s} \sim \left( \frac{T_e}{m_e} \frac{m_i}{\gamma_e T_e + \gamma_i T_i} \right)^{1/2} >> 1 \]
Thus, the electrons are communicating over many wavelengths during one wave period so that they remain isothermal; we therefore choose the isothermal \( \gamma_e = 1 \). When \( T_e >> T_i \), we then have the very simple and easy to remember formula
\[ c_s = \left( \frac{T_e}{m_i} \right)^{1/2} \] (7.96)
In other words, the sound speed is the thermal speed that the ions would have if they had the electron temperature.

Let us now return to a more exact solution of (7.86) to (7.90) that does not assume quasineutrality. Because the electron mass is very small, we ignore the electron "inertia" term on the left side of (7.87), upon which (7.87) yields
\[ \frac{\partial n_{ei}}{\partial x} = \frac{-en_0}{\gamma_e T_e} \frac{\partial E}{\partial x} \] (7.97)
For the ions, we eliminate \( V_i \) from the spatial derivative of (7.89) by using the time derivative of (7.88), to obtain
\[ -m_i \frac{\partial^2 n_{ii}}{\partial t^2} = -\gamma_i T_i \frac{\partial^2 n_{ii}}{\partial x^2} + \frac{en_0}{\gamma_e T_e} \frac{\partial E}{\partial x} \] (7.98)
Looking for plane wave solutions to (7.90), (7.97), and (7.98) (or Fourier transforming, if you like), we find
\[ ikE = 4\pi e(n_{ii} - n_{ei}) \] (7.99)
\[ ikn_{ei} = \frac{-en_0}{\gamma_e T_e} E \] (7.100)
and
\[ \left( \frac{\omega^2}{\omega^2 - k^2 \gamma_e T_e/m_i} \right) n_{ii} = \frac{en_0}{m_i} ikE \] (7.101)
Inserting (7.100) and (7.101) into (7.99) we find
\[ ik \left[ 1 - \frac{\omega_i^2}{\omega^2 - k^2 \gamma_e T_e/m_i} + \frac{\omega_e^2}{k^2 \gamma_e T_e/m_e} \right] E = 0 \] (7.102)
from which we identify the dielectric function
\[ \epsilon(\omega,k) = 1 - \frac{\omega_i^2}{\omega^2 - k^2 \gamma_e T_e/m_i} + \frac{\omega_e^2}{k^2 \gamma_e T_e/m_e} = 0 \] (7.103)
the zeros of which yield the dispersion relation \( \omega(k) \). Solving (7.103), we find
\[ \omega^2 = k^2 \frac{\gamma_e T_e}{m_i} + \frac{k^2 \gamma_e T_e/m_i}{1 + \gamma_e k^2 \kappa_e} \] (7.104)
which is the general dispersion relation for ion plasma waves.

**Exercise** Solve (7.103) to obtain (7.104).
In the small $k\lambda_e$ limit, we regain the ion-acoustic dispersion relation (7.95). We further expect that (7.104) is only valid when the second term on the right is larger than the first. If this were not so, we would have $\omega/k \sim (T_i/m_i)^{1/2} \sim v_p$ which would mean that many ions would have speeds of the same order as the wave phase speed. When this is the case, we do not expect fluid theory to be valid; rather, we must use the Vlasov equation to properly treat those particles which can interact resonantly with the wave.

Another interesting limit of (7.104) is reached when $T_i \to 0$ and $k\lambda_e \gg 1$; we then find

$$\omega^2 \approx \omega_i^2$$

which are ion plasma waves oscillating at the ion plasma frequency. Because the wavelength is short compared to the electron Debye length, the electrons are incapable of shielding, and we have ions oscillating in a uniform background of negative charge. This is quite analogous to our cold electron plasma oscillations at $\omega = \omega_s$, which are electrons oscillating in a uniform background of positive charge.

We can now draw the dispersion diagrams of electron plasma waves and ion plasma waves on the same diagram; we do this schematically for the case $T_i \to 0$ in Fig. 7.4. Note that the dispersive $(k^2\lambda_e^2)$ term in the denominator of (7.104) becomes more important at larger $k$, leading to a transition from the acoustic behavior at small $k$ (7.95) to the oscillations at $\omega = \omega_i$ (7.105) at large $k$.

### 7.6 ELECTROMAGNETIC WAVES

The only other waves in unmagnetized homogeneous plasma are electromagnetic waves. We shall find that these waves are high frequency, $\omega \geq \omega_e$, so that we can ignore ion motion. We shall further find that these waves are transverse, $\mathbf{k} \cdot \mathbf{E} = 0$ and $\mathbf{k} \cdot \mathbf{B} = 0$, so that we can ignore Poisson's equation and the $\nabla \cdot \mathbf{B} = 0$ equation. The fluid equations that we then need are
Fluid Equations

\[ \nabla \times \mathbf{E} = -\frac{1}{c} \partial_t \mathbf{B} \]  
(7.106)

\[ \nabla \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \partial_t \mathbf{E} \]  
(7.107)

\[ \mathbf{J} = -en_e \mathbf{V}_e \]  
(7.108)

\[ m_n \mathbf{V}_e \partial_t \mathbf{V}_e + m_n (\mathbf{V}_e \cdot \nabla) \mathbf{V}_e = -\nabla P_e - en_e \mathbf{E} - \frac{en_e}{c} \mathbf{V}_e \times \mathbf{B} \]  
(7.109)

\[ \partial_t n_e + \nabla \cdot (n_e \mathbf{V}_e) = 0 \]  
(7.110)

We have assumed that the wave is transverse, \( \mathbf{k} \cdot \mathbf{E} = 0 \). If \( \mathbf{k} \) is in the \( \hat{x} \)-direction, we may choose \( \mathbf{E} \) in the \( \hat{y} \)-direction; then by Faraday's law (7.106), we have \( \mathbf{B} \) along \( \hat{z} \) (Fig. 7.5). We next assume that there is no zero order component of \( \mathbf{V}_e \), and that we can neglect the \( \mathbf{V}_e \times \mathbf{B} \) force; this assumption must be checked at the end of the calculation. We look for solutions that have \( \mathbf{k} \cdot \mathbf{V}_e = 0 \); then (7.110) predicts \( \partial n_e / \partial t = 0 \), so \( n_e = n_0 \) everywhere and we can ignore \( \nabla P_e \) in (7.109). With no further assumption, the \( (\mathbf{V}_e \cdot \nabla) \mathbf{V}_e \) term in (7.109) also vanishes. We have left the equations

\[ \nabla \times \mathbf{E} = -\frac{1}{c} \partial_t \mathbf{B} \]  
(7.111)

\[ \nabla \times \mathbf{B} = -\frac{4\pi n_0}{c^2} \mathbf{E} + \frac{1}{c} \partial_t \mathbf{E} \]  
(7.112)

\[ m_n \partial_t \mathbf{V}_e = -en_e \mathbf{E} \]  
(7.113)

Taking the time derivative of (7.112) and the curl of (7.111), we eliminate \( \partial_t \mathbf{V}_e \) and \( \mathbf{B} \) in (7.112) to obtain

\[ -c\nabla \times (\nabla \times \mathbf{E}) = \frac{4\pi n_0 e^2}{m_e c} \mathbf{E} + \frac{1}{c} \frac{\partial^2 \mathbf{E}}{\partial t^2} \]  
(7.114)

or taking a plane wave solution, \( \nabla \times \nabla \times \rightarrow k^2 \), we get

Fig. 7.5 Vector relationships in an electromagnetic wave in unmagnetized plasma.
\[(\omega^2 - k^2c^2 - \omega_e^2)E = 0\] (7.115)

which yields the **electromagnetic dispersion relation**

\[\omega^2 = \omega_e^2 + k^2c^2\] (7.116)

Letting the plasma density approach zero we regain the free space light waves with \(\omega = kc\).

Note the similarity between the electromagnetic dispersion relation and the Langmuir dispersion relation, where \(c^2\) is replaced by \(3v_e^2\). On the same dispersion diagram, the two branches look as shown in Fig. 7.6.

Recall that in the theory of optical media (air, water, etc.) it is useful to define an index of refraction

\[n \equiv \frac{ck}{\omega}\] (7.117)

for light traveling through the medium. From (7.116) we see that in a plasma the index of refraction is

\[n \equiv \sqrt{\frac{\omega^2 - \omega_e^2}{\omega}} = \sqrt{1 - \omega_e^2/\omega^2}\] (7.118)

According to (7.118), the index of refraction becomes imaginary when \(\omega < \omega_e\). Thus, for real \(\omega\) one obtains imaginary \(k\), corresponding to evanescence. The result of this evanescence is that when an electromagnetic wave impinges on an inhomogeneous plasma, it reflects at the point where \(\omega = \omega_e\), called the position of **critical density**. This effect is important in laser fusion and in the interaction of radio waves with the ionosphere (Fig. 7.7).

We can now reconsider our neglect of the \((q/c)V_e \times B\) force in this derivation. By Faraday's law, \(B \sim (ck/\omega)E \sim nE\), but \(n < 1\) always by (7.118), so \(B < E\). Thus, \((q/c)|V_e \times B| < q|V_e/c||E|\) so that the magnetic force will always be

---

**Fig. 7.6** Dispersion diagram for electromagnetic waves and Langmuir waves in unmagnetized plasma.
negligible compared to the electric force as long as the motion produced by the electric field, $V_e$, is always nonrelativistic.

**EXERCISE** Sketch the group speed $d\omega /dk$ and the phase speed $\omega /k$, both vs. $k$, for electromagnetic waves.

This completes our discussion of linear fluid waves for uniform unmagnetized plasma. We have found only three different waves for a given wave number $k$: the ion plasma wave or ion-acoustic wave, the electron plasma wave or Langmuir wave, and the electromagnetic wave. The addition of inhomogeneity or a magnetic field will greatly multiply the number of linear modes, as we shall see shortly.

### 7.7 UPPER HYBRID WAVES

Up to this point we have considered waves in unmagnetized plasma. We now wish to consider linear waves in magnetized plasma. In general, there will be two important directions for any wave motion, the direction of the external magnetic field $\mathbf{B}_0$, and the direction of the wave number $\mathbf{k}$. Since we are looking for linear waves, there will be two important wave quantities, the first order electric field $\mathbf{E}_1$, and the first order magnetic field $\mathbf{B}_1$. There are six terms that are used to describe relations among the four quantities $\mathbf{B}_0$, $\mathbf{k}$, $\mathbf{E}_1$, and $\mathbf{B}_1$. If $\mathbf{k}$ is along $\mathbf{B}_0$, $\mathbf{k} \cdot \mathbf{B}_0 = 1$, we call the wave parallel; if $\mathbf{k} \cdot \mathbf{B}_0 = 0$ the wave is perpendicular. If $\mathbf{k} \cdot \mathbf{E}_1 = 1$ the wave is longitudinal, while if $\mathbf{k} \cdot \mathbf{E}_1 = 0$, the wave is transverse. When $\mathbf{B}_1 = 0$, the wave is electrostatic, while if $\mathbf{B}_1 \neq 0$ the wave is electromagnetic. Of course, not all waves deserve one or another of these terms; that is, a wave with $\mathbf{k}$ at a 45° angle to $\mathbf{B}_0$ is neither parallel nor perpendicular. We can often relate the last two terms using Faraday’s law $\nabla \times \mathbf{E}_1 = - (1/c) \partial_t \mathbf{B}_1$, or $\mathbf{k} \times \mathbf{E}_1 = (\omega/c)\mathbf{B}_1$. Since
for longitudinal waves, \( k \times E_1 = 0 \), thus the wave is electrostatic, and vice versa. Similarly, all transverse waves are electromagnetic (but not vice versa; why not?).

Let us first look for high frequency waves traveling across the magnetic field, with \( E_1 \cdot \hat{k} = 1 \); these perpendicular longitudinal electrostatic waves are known as upper hybrid waves. We take \( T_e = T_i = 0 \) and \( m_i \to \infty \); therefore the ions do not move, but form a fixed background of positive charge. The relevant equations are then

\[
\begin{align*}
\partial_t n_e + \nabla \cdot (n_e V_e) &= 0 \\
m_e n_e \partial_t V_e + m_e n_e V_e \cdot \nabla V_e &= -en_e E_1 - \frac{en_e}{c} V_e \times B \\
\nabla \cdot E_1 &= 4\pi e (n_0 - n_e)
\end{align*}
\]

(7.119) \hspace{1cm} (7.120) \hspace{1cm} (7.121)

**EXERCISE** Why aren't the other Maxwell equations relevant?

With \( E_1 = E_1 \hat{x}, k = k \hat{x}, B_0 = B_0 \hat{z} \), (7.120) will produce components of \( V_e \) in both the \( x \) and \( y \) directions, so \( V_e = (v_x, v_y, 0) \) (Fig. 7.8). Then linearizing (7.119) to (7.121) and looking for plane wave solutions yields

\[
\begin{align*}
-i\omega n_{e1} + ikn_0 v_x &= 0 \\
-i\omega m_e v_x &= -eE_1 - \frac{e}{c} v_y B_0 \\
-i\omega m_e v_y &= \frac{e}{c} v_x B_0
\end{align*}
\]

(7.122) \hspace{1cm} (7.123) \hspace{1cm} (7.124)

and

\[
i kE_1 = -4\pi en_{e1}
\]

(7.125)

Equations 7.122 and 7.125 yield \( v_x \) in terms of \( E_1 \), and (7.124) yields \( v_y \) in terms of \( v_x \); substituting the result into (7.123) yields

![Fig. 7.8 Vector orientations in an upper hybrid wave.](image-url)
Fluid Equations

\[
\left( \frac{-\omega^2}{\omega_e^2} + 1 + \frac{\Omega_e^2}{\omega_e^2} \right) E_1 = 0
\] (7.126)

from which, upon dividing out \( E_1 \), one obtains the dispersion relation

\[
\omega^2 = \omega_e^2 + \Omega_e^2 \equiv \omega_{\text{UL}}^2
\] (7.127)

for upper hybrid waves. As in the case of cold plasma waves with no magnetic field [to which (7.127) reduces when \( B_0 \rightarrow 0 \)] this frequency is independent of the wave number.

**EXERCISE** Obtain (7.126) as indicated.

Physically, these waves have a density variation similar to the cold plasma \((B_0 = 0)\) waves, but now the electrons are performing a sort of gyromotion in the wave; the electric field tries to make them move in the \( \hat{x} \)-direction, but the \( \mathbf{V}_e \times \mathbf{B}_0 \) force produces a velocity in the \( \hat{y} \)-direction. Suppose we take \( v_x = v_{x0} \exp(-i\omega t + ikx) \); then by (7.124) we have

\[
v_y = -i \frac{\Omega_e}{\omega} v_x = -i \frac{\Omega_e}{\omega} v_{x0} \exp(-i\omega t + ikx)
\] (7.128)

With \( v_{x0} \) real, we can obtain a real solution by adding this solution to its complex conjugate and multiplying by 1/2; we find

\[
v_x = v_{x0} \cos (kx - \omega t)
\] (7.129)

and

\[
v_y = \frac{\Omega_e}{\omega} v_{x0} \sin (kx - \omega t)
\] (7.130)

By (7.127), \( \Omega_e/\omega < 1 \) always, so \((v_y)_{\text{max}} < (v_x)_{\text{max}} \) always. Because the Lorentz force acts as an extra restoring force for the wave, the frequency is higher than the cold plasma \((B_0 = 0)\) wave. As the magnetic field \( B_0 \rightarrow 0 \) we regain the cold plasma wave, while as the density goes to zero \((\omega_e \rightarrow 0)\) we have a wave consisting of particles gyrating in the magnetic field, \((v_y)_{\text{max}} = (v_x)_{\text{max}}\).

### 7.8 ELECTROSTATIC ION WAVES

We next look for low frequency electrostatic waves whose physics is dominated by the ions. Because we are looking for electrostatic waves, the only one of Maxwell’s equations needed is Poisson’s equation. However, if we assume quasineutrality, \( n_{e1} \approx n_{i1} \), then we can avoid using Poisson’s equation, and we have only the four fluid equations (electron and ion continuity equations, electron and ion force equation). (Note that here with a low frequency wave, we assume \( n_{e1} \approx n_{i1} \) because the electrons have time to adjust to the ions; whereas in the previous section, the high frequency motions are dominated by \( n_{e1} \), and the massive ions do not have time to follow; therefore, \( n_{i1} \approx 0 \) and \( n_{e1} \neq n_{i1} \).) Thus, we need only the four fluid equations, which we linearize immediately, obtaining
\[ m_n \rho_e \partial_t V_e = - \gamma_T \nabla n_{e1} - e n_0 E - \frac{e n_0}{c} V_e \times B_0 \]  
(7.131)
\[ \partial_t n_{e1} + n_0 \nabla \cdot V_e = 0 \]  
(7.132)
\[ m_n \rho_i \partial_t V_i = - \gamma_T \nabla n_{e1} + e n_0 E + \frac{e n_0}{c} V_i \times B_0 \]  
(7.133)
\[ \partial_t n_{e1} + n_0 \nabla \cdot V_i = 0 \]  
(7.134)

where \( n_{e1}, V_e, V_i, \) and \( E \) are all first order quantities. We are interested in waves traveling at any angle to the magnetic field, which we take in the \( \hat{z} \) -direction. We can take the wave vector \( \vec{k} \) to lie in the \( x-z \) plane (Fig. 7.9).

Adding (7.131) to (7.133) to eliminate \( E \), one obtains
\[ -i \omega n_0 (m_e V_e + m_i V_i) = -i \vec{k} (\gamma_T V_e + \gamma_T V_i) n_{e1} \]
\[ + \frac{e n_0}{c} (V_i - V_e) \times B_0 \]  
(7.135)

Looking for plane wave solutions, taking the dot product of the wave number \( \vec{k} \) with (7.135), and inserting \( \vec{k} \cdot V_{e,i} = \omega n_{e1}/n_0 \) from (7.132) and (7.134), yields
\[ -i \omega n_0 (m_e + m_i) \omega n_{e1}/n_0 = -i k^2 (\gamma_T V_e + \gamma_T V_i) n_{e1} \]
\[ + \frac{e n_0}{c} \vec{k} \cdot [(V_i - V_e) \times B_0] \]  
(7.136)

The last term is
\[ \vec{k} \cdot [(V_i - V_e) \times B_0] = k_x (V_y - V_{ey}) B_0 \]  
(7.137)

In order to express \( V_{ey}, V_{by} \) in terms of \( n_{e1} \), we go back to (7.131) and take its cross product with the wave number \( \vec{k} \), obtaining
\[ -i \omega n_0 \rho_e (k \times V_e) = -\frac{e n_0}{c} \vec{k} \times (V_e \times B_0) \]  
(7.138)

or
\[ \vec{k} \times V_e = \frac{\Omega_f}{i \omega} \vec{k} \times (V_e \times \hat{z}) \]  
(7.139)

Fig. 7.9 Vector orientations in an electrostatic ion wave.
which gives three equations

\[ -V_{ex} k_z = i \frac{\Omega_e}{\omega} V_{ex} k_z \]  \hspace{1cm} (7.140)

\[ -k_x V_{ex} + V_{ez} k_z = i \frac{\Omega_e}{\omega} V_{ex} k_z \]  \hspace{1cm} (7.141)

and

\[ k_x V_{ex} = -i \frac{\Omega_i}{\omega} V_{ex} k_x \]  \hspace{1cm} (7.142)

These can be solved for \( V_{ex}, V_{ez} \) in terms of \( V_{ey} \),

\[ V_{ex} = \frac{i \omega}{\Omega_e} V_{ey} \]  \hspace{1cm} (7.143)

which is just what we had for the upper hybrid wave, and

\[ V_{ez} = -V_{ey} \frac{k_z}{k_x} i \frac{\Omega_e}{\omega} \left( 1 - \frac{\omega^2}{\Omega_e^2} \right) \]  \hspace{1cm} (7.144)

By the continuity equation (7.132),

\[ k_x V_{ex} + k_z V_{ez} = \omega n_{e1}/n_0 \]  \hspace{1cm} (7.145)

or

\[ \frac{\omega n_{e1}}{n_0} = \left[ k_x \left( \frac{i \omega}{\Omega_e} \right) + k_z \left( \frac{-i \Omega_i}{\omega} \right) \right] V_{ey} \]  \hspace{1cm} (7.146)

Finally, invert (7.146) for \( V_{ey} \), insert in (7.136), and obtain [ignoring \( m_e \ll m_i \) and using (7.137)]

\[ -i \omega^2 m_e n_{e1} = -ik^2(\gamma_e T_e + \gamma_i T_i)n_{e1} + \frac{e_n}{c} k_x B_0 \frac{\omega n_{e1}}{n_0} \]

\[ \times \left\{ \frac{1}{k_x \frac{i \omega}{\Omega_e} + k_z \frac{i \omega}{\omega} \left( 1 - \frac{\omega^2}{\Omega_i^2} \right)} - \frac{1}{k_x \frac{i \omega}{\Omega_e} + k_z \frac{i \omega}{\omega} \left( 1 - \frac{\omega^2}{\Omega_i^2} \right)} \right\} \]

(7.147)

where we have obtained \( V_{ey} \) by replacing \( \Omega_e \) with \( \Omega_i \) everywhere in (7.146).

**EXERCISE**  Justify the last step.

We can divide \( n_{e1} \) from every term in (7.147) to obtain the dispersion relation [with \( c_s^2 = (\gamma_e T_e + \gamma_i T_i)/m_i \) as usual]

\[ \frac{\Omega_i}{\omega} \left\{ \frac{1}{\frac{\omega}{\Omega_e} - \frac{k_z^2}{k_x^2} \left( 1 - \frac{\omega^2}{\Omega_i^2} \right)} - \frac{1}{\frac{\omega}{\Omega_i} - \frac{k_z^2}{k_x^2} \left( 1 - \frac{\omega^2}{\Omega_i^2} \right)} \right\} = 0 \]  \hspace{1cm} (7.148)
which is the dispersion relation for \textit{electrostatic ion waves}.

Let us look at this monster in various limits. First, let \( k \) be along \( \hat{B}_0 \), \( k = k_z \hat{z} \). Then \( k_z \to 0 \), and each denominator becomes infinite, provided \( \omega \neq \pm \Omega_e, \pm \Omega_i \). Then

\[
1 - \frac{k_x^2 c_s^2}{\omega^2} = 0 \tag{7.149}
\]

or

\[
\omega = \pm k_x c_s \tag{7.150}
\]

which is our old friend the ion-acoustic wave; we would have hoped to recover this wave for parallel propagation, since then the magnetic field does not influence the wave properties, and we should recover all unmagnetized waves. (The magnetic field may, however, affect the values of \( \gamma_r, \gamma_i \), which are now hidden in \( c_s \).)

We assumed \( \omega \neq \pm \Omega_e, \pm \Omega_i \). Let us return to consider that possibility. First, we let \( \omega \to \Omega_i \) in (7.148), and take the limit \( k_x \to 0 \). The first denominator becomes infinite, while the remainder of (7.148) yields

\[
1 - \frac{k_x^2 c_s^2}{\Omega_i^2} = \frac{1}{1 - \frac{k_x^2}{k_i^2} \left( 1 - \frac{\omega^2}{\Omega_i^2} \right)} = 0 \tag{7.151}
\]

Then we can allow \( k_x \to 0 \) and \( \omega \to \Omega_i \) in such a way that this equation is satisfied; that is, \( \omega = \Omega_i \) is a solution, and can be called an \textit{ion-cyclotron wave}.

**EXERCISE** Convince yourself that \( \omega = \Omega_e \) is also a solution as \( k_x \to 0 \); this is an \textit{electron-cyclotron wave}.

Let us now look in the other direction, at perpendicular propagation with \( k = k_x \hat{x} \). The limit \( k_z \to 0 \) in (7.148) yields

\[
1 - \frac{k_x^2 c_s^2}{\omega^2} + \frac{\Omega_i^2}{\omega^2} - \frac{\Omega_i^2}{\omega^2} = 0 \tag{7.152}
\]

Ignoring \( \Omega_i^2 \ll |\Omega_i \Omega_e| \), we find

\[
\omega^2 = k_x^2 c_s^2 + |\Omega_i \Omega_e| \tag{7.153}
\]

which are \textit{lower hybrid waves} propagating perpendicular to the magnetic field. For small \( k_x \), we have

\[
\omega = \sqrt{|\Omega_i \Omega_e|} = \omega_{\text{LH}} \tag{7.154}
\]

where \( \omega_{\text{LH}} \) is the \textit{lower hybrid frequency}.

The physical interpretation of lower hybrid waves is quite simple. Since \( \mathbf{E} \parallel \mathbf{k} \perp \mathbf{B}_0 \), we might suppose that the massive ions move along \( \mathbf{E} \), while the light electrons perform an \( \mathbf{E} \times \mathbf{B}_0 \) drift in the \( \hat{y} \)-direction. It turns out that the \( \hat{x} \) displacement of the ions is equal to the \( \hat{x} \) displacement of the electrons (because of the polarization drift) only if \( \omega = \omega_{\text{LH}} = \sqrt{|\Omega_i \Omega_e|} \).

**EXERCISE** Show that \( \omega = 0 \) is also a solution of (7.148) as \( k_z \to 0 \).
Fluid Equations

Let us now ask what happens if we are propagating almost, but not quite, perpendicular to \( \mathbf{B}_0 \), so that \( k_y \gg k_z \). Then, since we look for very low frequency waves, \( \omega \sim \Omega \), \( \omega/|\Omega| \ll 1 \), we discard all terms of order \( \omega/|\Omega| \). Equation (7.148) becomes

\[
1 - \frac{k^2 c_s^2}{\omega^2} - \frac{\Omega_i k_x^2}{\Omega_i k_z^2} - \frac{1}{\Omega_i^2} \left( 1 - \frac{\omega^2}{|\Omega|^2} \right) = 0 \quad (7.155)
\]

Suppose \( k_y/k_z \ll (m_e/m_i)^{1/2} \), then we can discard the third term compared to unity. Likewise, we can discard the term proportional to \( k_y/k_z \ll 1 \) in the denominator. We find

\[
1 - \frac{1}{\omega^2} (k^2 c_s^2 + \Omega_i^2) = 0 \quad (7.156)
\]

or

\[
\omega^2 = k^2 c_s^2 + \Omega_i^2 \quad (7.157)
\]

which is the dispersion relation for electrostatic ion cyclotron waves, valid for \( k_y/k_z \gg (m_e/m_i)^{1/2} \), that is, for an electron-proton plasma, at angles greater than 2° away from perpendicular to the magnetic field.

Let us summarize our results. Define an angle \( \theta \) as the angle between \( \mathbf{k} \) and \( \mathbf{B}_0 \), as in Fig. 7.9. Then we have found:

\[
\theta = 0, \quad k_x = 0: \quad \omega^2 = k^2 c_s^2 \quad \omega^2 = \Omega_i^2 \quad \omega^2 = \Omega_e^2 \quad (7.158)
\]

\[
\theta < \pi/2, \quad 1 \gg k_z/k_x \gg (m_e/m_i)^{1/2}: \quad \omega^2 = k^2 c_s^2 + \Omega_i^2 \quad (7.159)
\]

\[
\theta = \pi/2, \quad k_z = 0: \quad \omega^2 = k^2 c_s^2 + |\Omega_i \Omega_e| \quad \omega^2 = 0 \quad (7.160)
\]

We may suppose from (7.158) to (7.160), or by looking at the basic equation (7.148), that there are three branches of solutions.

### 7.9 ELECTROMAGNETIC WAVES IN MAGNETIZED PLASMAS

We wish to extend the treatment of electromagnetic waves in a uniform unmagnetized plasma (Section 7.6) to the case of a magnetized plasma. Because we again expect high frequency waves, we ignore ion motion. For simplicity, consider a cold plasma, \( T_e = 0 \). The relevant equations are then Maxwell’s equations together with the electron force equation, used to calculate the current. We have, linearizing immediately,

\[
m_e n_e \frac{\partial \mathbf{V}}{\partial t} = -en_0 \mathbf{E}_1 - \frac{e}{c} n_e \mathbf{V} \times \mathbf{B}_0 \quad (7.161)
\]

\[
\nabla \times \mathbf{E}_1 = -\frac{1}{c} \frac{\partial \mathbf{B}_1}{\partial t} \quad (7.162)
\]
\[ \nabla \times \mathbf{B}_1 = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{\partial \mathbf{E}_1}{\partial t} \quad (7.163) \]

\[ \mathbf{J} = -en_0 \mathbf{V} \quad (7.164) \]

where \( \mathbf{V} \equiv \mathbf{V}_e \). Since we already have as many equations as unknowns, we shall avoid using Poisson's equation or the electron continuity equation.

With the coordinate system shown in Fig. 7.10, let us first look for waves traveling perpendicular to \( \hat{B}_0 \), \( \mathbf{k} = k\hat{x} \). Then there are two possibilities: the electric field can be along \( \hat{B}_0 \) (the ordinary wave), and the electric field can be in the \( x-y \) plane, perpendicular to \( \hat{B}_0 \) (the extraordinary wave). In the first case, the electric field \( \mathbf{E}_1 = E_z \hat{z} \) induces an electron velocity in the \( z \)-direction, and the \( \mathbf{V}_e \times \mathbf{B}_0 \) force vanishes. Thus, Eqs. (7.161) to (7.164) reduce to the equivalent equations for an unmagnetized plasma, (7.111) to (7.113), and we can immediately write down the dispersion relation (7.116), which is

\[ \omega^2 = \omega_e^2 + k^2c^2 \quad (7.165) \]

which describes the ordinary wave; this wave propagates as if there were no magnetic field.

Next suppose the electric field is in the \( x-y \) plane. Then the electric field will create a \( \mathbf{V} \) in the \( x-y \) plane, and the \( \mathbf{V} \times \mathbf{B}_0 \) force will produce another component of velocity in the \( x-y \) plane; note, however, that no component of velocity is produced in the \( z \)-direction (Fig. 7.11). It is for this reason that we can consider the ordinary mode (7.165) and the extraordinary mode (currently being derived) separately.

![Fig. 7.10 Vector orientations for the "ordinary" electromagnetic wave in magnetized plasma.](image-url)
The relevant components of (7.161) to (7.164) become, with $E_1 = E_x \hat{x} + E_y \hat{y}$,

\[-i \omega m \psi_x = - eE_x - \frac{e}{c} V_z B_0 \]  \hspace{1cm} (7.166)

\[-i \omega m \psi_y = - eE_y + \frac{e}{c} V_z B_0 \]  \hspace{1cm} (7.167)

\[i k E_y = \frac{i \omega}{c} B_1 \]  \hspace{1cm} (7.168)

\[-i k B_1 = \frac{-4 \pi e n_0}{c} V_y - \frac{i \omega}{c} E_y \]  \hspace{1cm} (7.169)

\[0 = \frac{-4 \pi e n_0}{c} V_x - \frac{i \omega}{c} E_x \]  \hspace{1cm} (7.170)

**EXERCISE** Reconvince yourself that $\nabla \cdot A = i \mathbf{k} \cdot A$, $\partial_t A = - i \omega A$, and $\nabla \times A = i \mathbf{k} \times A$ if $A = A_0 \exp (-i \omega t + i \mathbf{k} \cdot \mathbf{x})$ where $A_0$ is a constant vector.

Equations (7.166) to (7.170) constitute five equations in five unknowns. From (7.168), $B_1 = (kc/\omega) E_y$; therefore, (7.169) and (7.170) yield for $V_x$, $V_y$,

\[V_x = \frac{-i \omega}{4 \pi n_0 e} E_x \]  \hspace{1cm} (7.171)

\[V_y = \left( \frac{ik^2 c^2}{4 \pi n_0 e \omega} + \frac{-i \omega}{4 \pi n_0 e} \right) E_y \]  \hspace{1cm} (7.172)
Inserting (7.171), (7.172) into (7.166), (7.167), we obtain

\[
\begin{bmatrix}
-i\omega m_{e} \left( \frac{-i \omega}{4 \pi n_{0} e} \right) + e & e \left( \frac{ik^{2}c^{2}}{4 \pi n_{0} e^{2} \omega} + \frac{-i \omega}{4 \pi n_{0} e} \right) \\
-eB_{0} \left( \frac{-i \omega}{4 \pi n_{0} e} \right) & -i\omega m_{e} \left( \frac{ik^{2}c^{2}}{4 \pi n_{0} e^{2} \omega} + \frac{-i \omega}{4 \pi n_{0} e} \right) + e
\end{bmatrix}
\begin{bmatrix}
E_{x} \\
E_{y}
\end{bmatrix}
= \begin{bmatrix}
0 \\
0
\end{bmatrix}
\] (7.173)

The determinant of the coefficients must vanish. Dividing each term by \( e \), we find

\[
\left( 1 - \frac{\omega^{2}}{\omega_{e}^{2}} \right) \left( 1 + \frac{k^{2}c^{2}}{\omega_{e}^{2} - \omega^{2}} \right) + \left( \frac{\omega \Omega_{e}}{\omega_{e}^{2}} \right) \Omega_{e} \left( \frac{-k^{2}c^{2}}{\omega_{e}^{2} \omega} - \frac{\omega}{\omega_{e}^{2}} \right) = 0
\] (7.174)

or

\[
\left( 1 - \frac{\omega^{2}}{\omega_{e}^{2}} \right) \left( 1 + \frac{k^{2}c^{2}}{\omega_{e}^{2} - \omega^{2}} \right) + \frac{\Omega_{e}^{2}k^{2}c^{2}}{\omega_{e}^{4}} - \frac{\omega^{2}\Omega_{e}^{2}}{\omega_{e}^{4}} = 0
\] (7.175)

which is the rather imposing dispersion relation for the extraordinary mode.

Separating a factor \( k^{2}c^{2}/\omega_{e}^{2} \) from (7.175) yields

\[
\frac{k^{2}c^{2}}{\omega_{e}^{2}} = \frac{\omega^{2}\Omega_{e}^{2}/\omega_{e}^{2} - \left( 1 - \frac{\omega^{2}}{\omega_{e}^{2}} \right)^{2}}{\left( 1 - \frac{\omega^{2}}{\omega_{e}^{2}} \right) + \frac{\Omega_{e}^{2}}{\omega_{e}^{2}}}
\] (7.176)

Multiplying (7.176) by \( \omega^{2}/\omega_{e}^{2} \) and recalling \( \omega_{U}^{2} = \omega_{e}^{2} + \Omega_{e}^{2} \) yields

\[
n^{2} = \frac{k^{2}c^{2}}{\omega^{2}} = \frac{\omega^{4} - 2\omega^{2}\omega_{e}^{2} + \omega^{4} - \omega^{2}\Omega_{e}^{2}}{\omega^{2} - \omega_{U}^{2}}
\]

\[
= \frac{\omega^{4} - 2\omega^{2}\omega_{e}^{2} + \omega^{2} \left( \omega^{2} - \omega_{U}^{2} \right)}{\omega^{2} \left( \omega^{2} - \omega_{U}^{2} \right)}
\] (7.177)

or

\[
n^{2} = \frac{k^{2}c^{2}}{\omega^{2}} = 1 - \frac{\omega_{e}^{2}}{\omega^{2}} \frac{\omega^{2} - \omega_{e}^{2}}{\omega^{2} - \omega_{U}^{2}}
\] (7.178)

for the extraordinary mode, where \( n \) is the index of refraction.

Equation (7.178) is the dispersion relation for the extraordinary mode, which is a perpendicular mode, partially transverse and partially longitudinal. It could be shown, by solving (7.178) for \( \omega \) and inserting in (7.173), that the components \( E_{x} \) and \( E_{y} \) are out of phase with each other, so that at a given point in space, the electric field vector performs a rotational motion as a function of time, as shown in Fig. 7.12.
Fig. 7.12 At a fixed spatial point, the electric field of an extraordinary wave rotates elliptically.

It is useful to define two properties of the X-mode (short for extraordinary; O-mode means ordinary mode). These are the cutoffs and the resonances. A cutoff is any frequency \( \omega \) at which \( k \to 0 \); thus, the cutoff frequencies are given by the zeros of the index of refraction (7.178). A resonance is any frequency for which the wave number \( k \to \pm \infty \); thus, we have a resonance whenever the denominator of (7.178) vanishes. [Some people remember the difference between cutoff \((k \to 0)\) and resonance \((k \to \infty)\) by the fact that \(c(k \to 0)\) comes before \(r(k \to \infty)\) in the alphabet.]

The resonances are easy; by (7.178) they happen at \( \omega = 0 \) and \( \omega = \omega_{UH} \). The cutoffs are obtained by setting (7.178) equal to zero. We find

\[
\omega^2 = \omega_e^2 \frac{\omega^2 - \omega_e^2}{\omega^2 - \omega_{UH}^2} \quad (7.179)
\]

or

\[
\omega^4 - \omega^2 \omega_{UH}^2 - \omega_e^2 \omega^2 + \omega_e^4 = 0 \quad (7.180)
\]

or

\[
\omega = \left[ \frac{\omega_{UH}^2 + \omega_e^2}{2} \pm \frac{1}{2} \sqrt{(\omega_{UH}^2 + \omega_e^2)^2 - 4 \omega_e^4} \right]^{1/2} \quad (7.181)
\]

Recalling \( \omega_{UH}^2 = \omega_e^2 + \Omega_e^2 \), we see that the inner radical is \(4 \omega_e^2 \Omega_e^2 + \Omega_e^4\); thus,

\[
\omega = \left[ \omega_e^2 + \frac{\Omega_e^2}{2} \pm \Omega_e \sqrt{\omega_e^2 + \Omega_e^2/4} \right]^{1/2} \quad (7.182)
\]

or

\[
\omega \left( \frac{k}{\kappa} \right) = \pm \frac{\Omega_e}{2} + \sqrt{\omega_e^2 + \Omega_e^2/4} \quad (7.183)
\]
where \( L, R \) refer to left and right, for reasons that will become clear in Section 7.10. (Recall that \( \Omega_e < 0 \).)

**EXERCISE** Demonstrate the equivalence of (7.182) and (7.183).

We see that \( \omega_L \) is somewhat below \( \omega_e \), and \( \omega_R \) is somewhat above \( \omega_e \). With this knowledge of cutoffs and resonances, we are able to draw the dispersion diagram for the extraordinary mode, using (7.178) to tell us if a resonance is for \( k^2 \rightarrow +\infty \) or \( k^2 \rightarrow -\infty \), and if a cutoff is for \( k^2 \rightarrow 0^+ \) or \( k^2 \rightarrow 0^- \). For completeness, our diagram can include the ordinary mode, which by (7.165) is

\[
\frac{n^2}{\omega^2} = \frac{k^2 c^2}{\omega^2} = 1 - \frac{\omega_e^2}{\omega^2}
\]

(7.184)

for the ordinary mode, which has a cutoff at \( \omega = \omega_e \) and a resonance at \( \omega = 0 \). Both dispersion diagrams are sketched in Fig. 7.13. Unlike previous dispersion diagrams, which are frequency \( \omega \) vs. wave number \( k \), Fig. 7.13 is a sketch of the square of the index of refraction \( n^2 = c^2 k^2 / \omega^2 \) vs. frequency \( \omega \).

**EXERCISE** Is Fig. 7.13 accurate for low frequencies \( \omega << \omega_L \)? Why not?

We could also solve (7.178) and (7.184) for the usual dispersion function \( \omega = \omega(k) \). A sketch of this function for both modes is shown in Fig. 7.14.

We note that Fig. 7.13 shows a frequency for every \( n^2 = k^2 c^2 / \omega^2 \), while in Fig. 7.14 there are regions of frequency where there are no waves. Why is this? It is because in certain regions, \( n^2 = k^2 c^2 / \omega^2 < 0 \) for real \( \omega \); thus \( k \) is imaginary. These waves are therefore evanescent, and they do not appear in Fig. 7.14, which is a sketch of real \( \omega \) vs. real \( k \). The bands where there are no propagating waves (\( 0 < \omega < \omega_e \) for the \( O \)-mode; \( 0 < \omega < \omega_L \) and \( \omega_{UL} < \omega < \omega_e \) for the \( X \)-mode) are called stop bands from radio engineering, while the other bands are called pass bands.

![Dispersion diagram for the extraordinary (X) mode and the ordinary (O) mode.](image-url)
7.10 ELECTROMAGNETIC WAVES ALONG $B_0$

Continuing our discussion of electromagnetic waves in magnetized plasma, we next look for parallel waves, traveling along $B_0$. We need only three basic equations: Ampere's law, Faraday's law, and the electron force equation (ignoring electron temperature and ion motion). These are, Fourier transforming and linearizing immediately,

$$ik \times E_1 = \frac{i \omega}{c} B_1$$  \hspace{1cm} (7.185)

$$ik \times B_1 = -\frac{4\pi n_0 e}{c} V - \frac{i \omega}{c} E_1$$  \hspace{1cm} (7.186)

and

$$-i \omega m_e V = -e E_1 - \frac{e}{c} V \times B_0$$  \hspace{1cm} (7.187)

where $V \equiv V_e$. Referring to Fig. 7.15, we see that a consistent solution to (7.185)–(7.187) is one that has $V$, $E_1$, and $B_1$ all in the $x$-$y$ plane with $k = k_2$ along $\hat{B}_0$. When we take $E_1 = (E_x, E_y, 0)$, $B_1 = (B_x, B_y, 0)$, and $V = (v_x, v_y, 0)$, Eqs. (7.185) to (7.187) yield

$$-ik E_y = \frac{i \omega}{c} B_x$$  \hspace{1cm} (7.188)

$$ik E_x = \frac{i \omega}{c} B_y$$  \hspace{1cm} (7.189)

$$-ik B_y = \frac{-4\pi n_0 e}{c} v_x - \frac{i \omega}{c} E_x$$  \hspace{1cm} (7.190)

$$ik B_x = \frac{-4\pi n_0 e}{c} v_y - \frac{i \omega}{c} E_y$$  \hspace{1cm} (7.191)

$$-i \omega m_e v_x = -e E_x - \frac{e}{c} B_0 v_y$$  \hspace{1cm} (7.192)
and

\[-i\omega m_e v_y = -eE_y + \frac{e}{c} B_0 v_x\] (7.193)

Inserting (7.188) and (7.189) for \(B_x, B_y\), in (7.190) and (7.191), we find

\[v_x = \left(\frac{-ik^2 c}{\omega} + \frac{i\omega}{c}\right) E_x -4\pi n_0 e/c\] (7.194)

and

\[v_y = \left(\frac{-ik^2 c}{\omega} + \frac{i\omega}{c}\right) E_y -4\pi n_0 e/c\] (7.195)

Inserting (7.194), (7.195) in (7.192), (7.193), we obtain for \(E_x, E_y\), the matrix equation

\[
\begin{bmatrix}
-i\omega m_e & -eB_0 & 0 \\
\frac{-ik^2 c}{\omega} + \frac{i\omega}{c} & \frac{-ik^2 c}{\omega} + \frac{i\omega}{c} & 0 \\
-\frac{eB_0}{c} & -\frac{eB_0}{c} & \frac{-ik^2 c}{\omega} + \frac{i\omega}{c} + \frac{eB_0}{c}
\end{bmatrix}
\begin{pmatrix}
E_x \\
E_y \\
0
\end{pmatrix}
= \begin{pmatrix}
0 \\
0 \\
0
\end{pmatrix}
\] (7.196)

Setting the determinant of the coefficients equal to zero, we find

\[
\left(1 + \frac{k^2 c^2}{\omega_e^2} - \frac{\omega^2}{\omega_e^2}\right)^2 = \frac{\Omega_e^2}{\omega_e^4} \left(\frac{\omega - k^2 c^2}{\omega}\right)^2
\] (7.197)

Fig. 7.15 Vector orientations for parallel (along \(\hat{B}_0\)) electromagnetic waves.
We take the square root of (7.197), retaining both signs, to obtain

\[ 1 - \frac{\omega}{\omega_c^2} \left( \omega - \frac{k^2 c^2}{\omega} \right) = \pm \frac{\Omega_e}{\omega_c^2} \left( \omega - \frac{k^2 c^2}{\omega} \right) \]  
(7.198)

or

\[ 1 = \left( \frac{\omega}{\omega_c^2} \pm \frac{\Omega_e}{\omega_c^2} \right) \left( \omega - \frac{k^2 c^2}{\omega} \right) \]  
(7.199)

or

\[ n^2 \equiv \frac{k^2 c^2}{\omega^2} = 1 - \frac{\omega_e^2/\omega^2}{1 \pm \Omega_e/\omega} \]  
(7.200)

which is the index of refraction for electromagnetic waves traveling along the magnetic field.

**EXERCISE** Verify all steps leading to (7.200).

Recalling \( \Omega_e < 0 \), the top sign in (7.200) is called the \( R \)-wave, meaning right circularly polarized, while the bottom sign is called the \( L \)-wave, meaning left circularly polarized. These terms come from the rotation of the electric field vector as the wave propagates (the right-hand rule places the thumb along \( k \) and the fingers in the direction of the \( E \) rotation for the \( R \)-wave; and opposite for the left wave; see Fig. 7.16). Because this situation is cylindrically symmetric about \( \hat{B}_0 \), the \( E_1 \) vector describes a circle, rather than an ellipse as in the \( X \)-mode case.

Note that the direction of rotation of the \( R \)-wave corresponds to the direction of gyration of electrons. Further note that when \( \omega = |\Omega_e| \), the \( R \)-wave has \( 1 + (\Omega_e/\omega) = 0 \), which by (7.200) is a resonance, \( k \to \infty \). Thus we see a physical

\[ \text{Fig. 7.16 Rotation of } \hat{E}_1 \text{ in a right circularly polarized wave (R) and in a left circularly polarized wave (L).} \]
connection between a resonance \((k \to \infty)\), and a resonance between the wave and the electrons; the electric field of the \(R\)-wave will continuously accelerate electrons when \(\omega = -\Omega_e\).

From (7.200) we see that the \(L\)-wave has no resonances; this makes physical sense because the \(L\)-wave rotates in the direction opposite to the gyration of electrons. The cutoffs are obtained by setting \(k = 0\) in (7.200); we find

\[
\omega_{R_L} = \pm \frac{\Omega_e}{2} + \sqrt{\omega_e^2 + (\Omega_e^2/4)} \tag{7.201}
\]

as the cutoffs for the \(R\)-wave and the \(L\)-wave. These are precisely the cutoffs found for the extraordinary mode, Eq. (7.183), and we now understand why we called them the left and right cutoffs. We note from (7.201) that one always has \(\omega_R > |\Omega_e|\) and \(\omega_R > \omega_L\). However, for \(\omega_L\) and \(|\Omega_e|\), there are two possibilities: \(\omega_L > |\Omega_e|\), and \(\omega_L < |\Omega_e|\).

**EXERCISE** Show that \(\omega_L = |\Omega_e|\) when \(\omega_e = 2^{1/2}|\Omega_e|\).

The dispersion diagrams are different in the two cases. These are found in Ref. [3], p. 195. The dispersion relation \(\omega = \omega(k)\) is shown in Fig. 7.17 for the case \(\omega_L > |\Omega_e|\). Note that the \(R\)-wave has two "pass bands," \(0 < \omega < |\Omega_e|\), and \(\omega > \omega_R\), separated by a "stop band." The \(L\)-wave exists only for \(\omega > \omega_L\). Both high frequency branches asymptote to \(\omega = kc\) at high frequencies. The locations of the pass and stop bands can be seen more clearly by drawing \(n^2 = k^2c^2/\omega^2\) vs. \(\omega\), as shown in Fig. 7.18 (see Ref. [3], p. 194). The low frequency branch of the \(R\)-wave is often called the electron-cyclotron wave. Once again, the "stop bands" occur where \(n^2 < 0\) and the "pass bands" occur when \(n^2 > 0\). (Do we trust this theory for low frequencies \(\omega < \Omega_e\)?)

For the low density plasma, \(\omega_L < |\Omega_e|\), the character of the dispersion relation \(\omega = \omega(k)\) changes, as shown in Fig. 7.19 (see Ref. [3], p. 195). The low frequency branch of the \(R\)-wave is again called the electron-cyclotron wave.

![Dispersion diagram for parallel electromagnetic waves for the case \(\omega_L > |\Omega_e|\).](image-url)
From Fig. 7.19 we can see that the electron-cyclotron wave has a portion where $V_g = \frac{d\omega}{dk}$ increases as $\omega$ increases. This is called the whistler wave, because the high frequency components of a wave packet travel faster than its low frequency components. An observer some distance away from a source (a lightning stroke, for example) will then hear a whistle starting at high frequencies and descending to lower frequencies.

In both of our dispersion diagrams, the $R$-wave at very high frequencies is seen to have a higher phase speed than the $L$-wave. Thus, if a plane wave is incident on
a plasma along $\hat{B}_0$, its two normal mode components, $R$ and $L$, travel at different speeds, and the plane of polarization of the plane wave rotates as it travels. This is known as Faraday rotation, and is useful in measuring plasma densities in laboratory plasma and in interstellar space.

This completes our discussion of high frequency electromagnetic waves (ignoring ion motion) traveling in a magnetized plasma. We have discussed only waves traveling across $\hat{B}_0$ (O-mode and X-mode) and along $\hat{B}_0$ (R-wave and L-wave). Of course, waves can travel at any angle to $\hat{B}_0$. When they do, there will be two modes for any angle of propagation, and their properties will be some combination of the properties of the $O$, $X$, $R$, and $L$ waves.

7.11 ALFVÉN WAVES

Up until this point, we have considered electromagnetic waves ignoring ion motion, and ion waves that were electrostatic and thus ignored electromagnetic effects. Let us next combine ion motion with electromagnetic effects; we shall find parallel Alfvén waves ($k \parallel \hat{B}_0$) and perpendicular magnetosonic waves ($k \perp \hat{B}_0$).

First we look for low frequency waves traveling along $\hat{B}_0$. For simplicity we take a cold plasma, $T_i = T_e = 0$. We can also ignore electron inertia ($m_e \rightarrow 0$). Just as in the case of $R$-waves and $L$-waves, we look for waves with $k = k\hat{z}$, $B_0 = B_0\hat{z}$, and $V_e, V_i, E_1, B_1$ all in the $x$-$y$ plane (Fig. 7.20). Unlike the $R$, $L$-wave case, we do not look for a rotating $E_1, B_1$; rather, we take $E_1 = E_x\hat{x}$ and $B_1 = B_y\hat{y}$. As we shall see, this form for $E_i$ and $B_i$ is not entirely self-consistent. The relevant fluid equations are then (linearizing and Fourier transforming immediately):

![Fig. 7.20 Vector orientations in an Alfvén wave.](image-url)
\[ i \mathbf{k} \times \mathbf{E}_i = \frac{i\omega}{c} \mathbf{B}_i \] (7.202)

\[ i \mathbf{k} \times \mathbf{B}_i = \frac{4\pi}{c} n_0 e (\mathbf{V}_i - \mathbf{V}_e) - \frac{i\omega}{c} \mathbf{E}_i \] (7.203)

\[ 0 = - en_0 \mathbf{E}_i - \frac{en_0}{c} \mathbf{V}_e \times \mathbf{B}_0 \] (7.204)

\[ -i\omega m_0 \mathbf{V}_i = en_0 \mathbf{E}_i + \frac{en_0}{c} \mathbf{V}_i \times \mathbf{B}_0 \] (7.205)

Considering the motions of individual electrons, we are keeping the electron drift in the \( \hat{y} \)-direction, while ignoring the polarization drift in the \( \hat{x} \)-direction. We recall from Chapter 2 that the polarization drift speed is proportional to mass. Thus, for the ions, we have an \( \mathbf{E}_i \times \mathbf{B}_0 \) drift in the \( \hat{y} \)-direction, which approximately equals the electron drift and prevents any current in the \( \hat{y} \)-direction. We also have for the ions a component of velocity in the \( \hat{x} \)-direction (a polarization drift) that provides the current \( n_0 e (\mathbf{V}_i - \mathbf{V}_e) \) in (7.203) to drive the magnetic field \( \mathbf{B}_1 \). The approximation in this derivation is to ignore that portion of \( V_{e0} \) due to the \( V_{es} \times \mathbf{B}_0 \) force.

With this introduction, we write the relevant components of (7.202) to (7.205) as

\[ -\frac{i k^2 c}{\omega} E_x = \frac{4\pi n_0 e}{c} V_{ix} - \frac{i\omega}{c} E_x \] (7.206)

\[ -i\omega m_1 V_{ix} = eE_x + \frac{e}{c} V_{iy} B_0 \] (7.207)

and

\[ -i\omega m_1 V_{iy} = - \frac{e}{c} V_{ix} B_0 \] (7.208)

Solving (7.208) for \( V_{iy} \), we find

\[ V_{iy} = - \frac{i\Omega_i}{\omega} V_{ix} \] (7.209)

We insert (7.209) in (7.207) to obtain

\[ V_{ix} = \left( -\frac{e/m_1}{-i\omega + i\Omega_i^2/\omega} \right) E_x \] (7.210)

Combining (7.210) and (7.206) then yields the dispersion relation

\[ 1 - \frac{k^2 c^2}{\omega^2} + \frac{\omega_i^2}{\Omega_i^2 - \omega^2} = 0 \] (7.211)

Enforcing the assumption \( \omega \ll \Omega_i \), implicit in the above discussion, we ignore \( \omega^2 \ll \Omega_i^2 \) in the second denominator, finding

\[ \omega^2 = \frac{k^2 c^2}{1 + \omega_i^2/\Omega_i^2} = \frac{k^2 c^2}{1 + 4\pi\rho_m c^2/B_0^2} \] (7.212)

where \( \rho_m \equiv n_0 m_1 \) is the ion mass density. If we define the Alfvén speed \( V_A \equiv (B_0^2/4\pi\rho_m)^{1/2} \), (7.212) is
\[ \omega^2 = \frac{k^2c^2}{1 + (c^2/V_A^2)} \]  
(7.213)

Multiplying top and bottom by \( V_A^2/c^2 \) we finally obtain

\[ \omega^2 = \frac{k^2V_A^2}{1 + (V_A^2/c^2)} \]  
(7.214)

as the dispersion relation for Alfvén waves. Note that for \( V_A \ll c \), this is \( \omega = kV_A \); therefore we have an acoustic dispersion relation. Recall that acoustic waves in air have an acoustic speed \( (P/\rho_m)^{1/2} \) where \( P \) is pressure; here we have a speed \( V_A = (B_0^2/4\pi\rho_m)^{1/2} \), which is of the same form if we relate \( B_0^2/4\pi \) to a magnetic pressure.

The physical interpretation of Alfvén waves is very interesting. We have seen that electrons and ions are \( E \times B \), drifting together in the \( \hat{y} \)-direction, with speed \( -(E_y/B_0)c \). Thus, both plasma fluids move together in the \( \hat{y} \)-direction. Now what is happening to magnetic field lines? They are being distorted by the addition of \( B_1 = B_0 \hat{z} \) to the background magnetic field \( B_0 = B_0 \hat{z} \), as shown in Fig. 7.21. The position function of a magnetic field line can be defined as

\[ Y_B(z,t) = \int_{z}^{z'} \frac{B_y(z',t)}{B_0} \, dz' \]  
(7.215)

Then the \( \hat{y} \) velocity \( V_B \) of a magnetic field line is the time derivative of \( Y_B \), or [with \( B_y \sim \exp(-i\omega t + ikz) \)]

\[ V_B = -i\omega \int z' \frac{B_y}{B_0} \, dz' = \frac{-i\omega}{ik} \frac{B_y}{B_0} \]  
(7.216)

Now from (7.202) and Fig. 7.20 we have

\[ B_y = \frac{ck}{\omega} E_x \]  
(7.217)

or

\[ V_B = -(E_y/B_0)c \]  
(7.218)

which is precisely the \( \hat{y} \)-velocity of fluid flow. Thus, in the \( \hat{y} \)-direction, we say that the particles are frozen to the field lines. This concept will prove useful later.

![Fig. 7.21 Total magnetic field in an Alfvén wave.](image-url)
(Chapter 8) for other low frequency plasma motions. Note that in the $\hat{z}$-direction, we can take the fluid speed and the field line speed both to be zero, satisfying this concept. However, in the $\hat{x}$-direction, we have seen that $V_{ex} \approx 0$ while $V_{ix} \neq 0$. Thus, we cannot have both kinds of particles frozen to the field lines in the $\hat{x}$-direction.

One may recall that the wave equation of a stretched string is $\omega = kc_T$ with $c_T = \sqrt{T/\rho_m}$, where $T$ is the tension on the string and $\rho_m$ is the mass per unit length. If we identify $B^2/4\pi$ as a tension per unit area and $\rho_m$ as a mass per unit volume, then the Alfvén wave dispersion relation $\omega = kV_A$ can be thought of as representing the wave that propagates when a field line, loaded with plasma, is plucked in the transverse direction.

### 7.12 FAST MAGNETOSONIC WAVE

The Alfvén wave of the previous section is a low frequency parallel electromagnetic wave, traveling along $\hat{B}_0$. Let us now look for a low frequency perpendicular electromagnetic wave, traveling across $\hat{B}_0$; this is the fast magnetosonic wave.

For simplicity, consider a cold plasma, $T_e = T_i = 0$, and ignore electron inertia, $m_e \rightarrow 0$. We look for a wave with $k \cdot \mathbf{B}_0 = 0$, $k \cdot \mathbf{E}_1 = 0$, and $\mathbf{E}_1 \cdot \mathbf{B}_0 = 0$, as in Fig. 7.22.

**Exercise** Why don't we look for low frequency waves with $\mathbf{E}_1$ along $\mathbf{B}_0$?

Have we ever looked for a wave with $\mathbf{E}_1$ along $\mathbf{B}_0$? What did we find?

We choose $k = k\hat{y}$, $\mathbf{E}_1 = E_1\hat{x}$, and $\mathbf{B}_1 = B_1\hat{z}$; thus $\mathbf{B}_1$ is along $\mathbf{B}_0$, and the relevant fluid equations, linearized and Fourier transformed, are

$$i k \times \mathbf{E}_1 = \frac{i \omega}{c} \mathbf{B}_1$$  \hspace{1cm} (7.219)

![Fig. 7.22 Vector orientations in a fast magnetosonic wave.](image-url)
\[ ik \times B_1 = \frac{4\pi}{c} n_0 e (V_i - V_e) - \frac{i\omega}{c} E_1 \]  
(7.220)

\[ 0 = -en_0 E_1 - \frac{en_0}{c} V_e \times B_0 \]  
(7.221)

\[ -i\omega m_e n_0 V_i = en_0 E_1 + \frac{en_0}{c} V_i \times B_0 \]  
(7.222)

From (7.221) we see that the electrons will have only an \( E_1 \times B_0 \) drift in the \( \hat{k} \)-direction, while the ions, for very small \( \omega \), will have approximately the same \( E_1 \times B_0 \) drift in the \( \hat{k} \)-direction. The ions, however, will have an extra component of velocity in the \( \hat{x} \)-direction, along \( \hat{E}_1 \), because of the polarization drift, which produces a current in the \( \hat{x} \)-direction that produces the perturbed magnetic field in the \( \hat{z} \)-direction. The relevant components of (7.219) to (7.222) are then

\[ -ik E_1 = \frac{i\omega}{c} B_1 \]  
(7.223)

\[ ik B_1 = \frac{4\pi n_0 e}{c} V_{ix} - \frac{i\omega}{c} E_1 \]  
(7.224)

\[ -i\omega m_e V_{ix} = eE_1 + \frac{e}{c} V_0 B_0 \]  
(7.225)

\[ -i\omega m_e V_{io} = -\frac{e}{c} V_{ix} B_0 \]  
(7.226)

These equations are identical to (7.206) to (7.209) for the Alfvén waves, and we can immediately write the dispersion relation (7.214) for small frequencies; this is

\[ \omega^2 = \frac{k^2 V_A^2}{1 + V_A^2/c^2} \]  
(7.227)

for the fast magnetoionic wave traveling across \( \hat{B}_0 \).

This completes our discussion of linear wave equations in infinite uniform plasma. We have often looked at parallel and perpendicular waves; in practice, waves can propagate at any angle to the magnetic field. Waves propagating at an arbitrary angle usually have some combination of the properties of the corresponding parallel wave and the corresponding perpendicular wave. Because of the complexity of these waves, we shall not derive all of their properties here. However, a useful qualitative device exists for thinking about these waves. This is called the CMA diagram, after its inventors Clemmow, Mullaly, and Allis [4, 5]. The diagram is valid only for cold plasmas, \( T_i = T_e = 0 \). It shows all of the waves that can propagate at a given angle to the magnetic field for any combination of density and magnetic field intensity. This useful diagram is discussed in Refs. [6] and [7].

In the next section, we turn our attention from linear waves characterized by a real frequency and a real wave number, to linear instabilities characterized by a complex frequency and a real wave number.
7.13 TWO-STREAM INSTABILITY

Previous sections of this chapter have treated examples of linear waves that arise from the fluid theory of plasma. These waves are characterized by a real frequency and a real wave number, and would all be excited if a magnetized Maxwellian plasma were perturbed. When a plasma does not consist of Maxwellian electrons and Maxwellian ions, some of the waves (normal modes) of the system can become unstable. This subject is treated within the Vlasov theory in Section 6.9. Within the fluid theory, unstable normal modes can arise whenever the zero order electron and ion velocities are different, or whenever one species consists of two or more components each with different zero order velocities. Such instabilities are called streaming instabilities.

As an example of a streaming instability, consider a plasma in which the ions are stationary, while the electrons are traveling with speed $V_0$. The linearized fluid equations are then

\[
\begin{align*}
\partial_t n_{e1} + n_0 \partial_x V_{e1} + V_0 \partial_x n_{e1} &= 0 \quad (7.228) \\
m_e n_0 \partial_t V_{e1} + m_e n_0 V_0 \partial_x V_{e1} &= -e n_0 E \quad (7.229) \\
\partial_t n_{i1} + n_0 \partial_x V_{i1} &= 0 \quad (7.230) \\
m_i n_0 \partial_t V_{i1} &= e n_0 E \quad (7.231)
\end{align*}
\]

and

\[
\partial_t E = 4\pi e (n_{i1} - n_{e1}) \quad (7.232)
\]

where we have assumed one-dimensional motions and $T_e = T_i = 0$, and the zeroth order speed $V_0$ contributes an extra term in (7.228) and in (7.229). Because we have no reason to suspect that the oscillations found here will be low frequency, we keep Poisson's equation (7.232) and we do not assume quasineutrality. In fact, if we allow $m_i \to \infty$ in (7.231), we would simply obtain the drifting cold plasma waves discussed in Problem 7.4; these are high frequency waves that become Langmuir waves in the limit that the drift speed $V_0 \to 0$. Here, we keep $m_i$ large but finite and show that the drifting cold plasma waves are unstable; that is, when the frequency $\omega$ is obtained from (7.228) to (7.232), one finds $\text{Im}(\omega) > 0$; thus $\exp(-i\omega t) \sim \exp[\text{Im}(\omega)t]$, which grows exponentially with time. Since no instability is found in Problem 7.4, it must be the case that $\text{Im}(\omega) \to 0$ as $m_i \to \infty$.

Fourier transforming (7.228) to (7.232), Eq. (7.229) yields

\[
(-i\omega + ikV_0)V_{e1} = -eE/m_e
\]

which when inserted in (7.228) yields

\[
(-i\omega + ikV_0)n_{e1} - \frac{ikn_0 eE/m_e}{-i\omega + ikV_0} = 0
\]

while (7.231) in (7.230) yields

\[
-i\omega n_{i1} = \frac{ikn_0 eE/m_i}{-i\omega}
\]

Then using (7.234) and (7.235) in Poisson's equation (7.232), we find the dispersion relation.
\[ ik = 4\pi e \left( \frac{ikn_0 e}{m_i \omega^2} + \frac{ikn_0 e}{m_i (\omega - kV_0)^2} \right) \]  
(7.236)

or

\[ \epsilon(k, \omega) = 1 - \frac{\omega_i^2}{\omega^2} - \frac{\omega_e^2}{(\omega - kV_0)^2} = 0 \]  
(7.237)

where we have identified the dielectric function \( \epsilon(k, \omega) \) (see Section 7.4). In the limit \( m_i \to \infty, \omega_i = 0 \), we find

\[ \omega = kV_0 \pm \omega_e \]  
(7.238)

in agreement with Problem 7.4.

With \( m_i \) finite, Eq. (7.237) is a quartic equation in \( \omega \), with four roots. Since (7.237) is a real equation, the complex conjugate of any root is also a root. (Why?) Thus, if we find any complex roots, either that root or its complex conjugate will have \( \text{Im}(\omega) > 0 \), and there will be an instability.

Let us use enlightened guessing to solve (7.237). Since the ions are important, we look for a wave such that the frequency is low in the laboratory frame [e.g., \( kV_0 \approx \omega_e \) and the lower sign in (7.238)]. However, low frequency means only \( |\omega| << \omega_e \); a vigorous instability could well lead to \( |\omega| >> \omega_e \). Let us then look for a solution (possibly complex) to (7.237) that satisfies \( \omega_i \ll |\omega| \ll \omega_e \).

Then, because the second term in (7.237) is much less than unity, in order to cancel the first term we must have the third term close to unity; this leads us to look at wave numbers \( k \) such that \( kV_0 = \omega_e \). Then (7.237) yields

\[
0 = 1 - \frac{\omega_i^2}{\omega^2} - \frac{\omega_e^2}{(\omega - \omega_e)^2}
= 1 - \frac{\omega_i^2}{\omega^2} - \frac{1}{(1 - \omega/\omega_e)^2}
\approx 1 - \frac{\omega_i^2}{\omega^2} - \left( 1 + \frac{2\omega}{\omega_e} \right)
= - \frac{\omega_i^2}{\omega^2} - \frac{2\omega}{\omega_e}
\]  
(7.239)

or

\[ \omega^2 = - \frac{1}{2} \omega_i^2 \omega_e \]  
(7.240)

or

\[
\frac{\omega}{\omega_e} = \left( -\frac{1}{2} \right)^{1/3} \left( \frac{m_i}{m_e} \right)^{1/3}
\]  
(7.241)

which represents instability since one of the three values of \((-1)^{1/3}\) is \((1/2) + i(3^{1/2}/2)\). In the frame moving with the electrons, the Doppler shifted frequency is \( \omega' = \omega - kV_0 \); since \( kV_0 = \omega_e \) and \( |\omega| \ll \omega_e \) this is roughly \( \omega' \approx -\omega_e \), so that the electrons see an oscillation at nearly their natural frequency of oscillation.
There is another useful way to determine that (7.237) yields instability. From (7.237) we define

\[ F(k, \omega) \equiv \frac{\omega_i^2}{\omega^2} + \frac{\omega_e^2}{(\omega - kV_0)^2} \]  \hspace{1cm} (7.242)

We can plot this function versus real frequency \( \omega \) at fixed wave number \( k \), as sketched in Fig. 7.23. From (7.242) and the illustration we see that when the line at unity intersects the graph of \( F(k, \omega) \) at four different points, there are four real roots and no instability for the chosen value of \( k \). However, suppose the central minimum of \( F(k, \omega) \) occurs at a value greater than unity; then there are only two real roots, as shown in Fig. 7.24. To determine when this happens, we determine when

\[ F_{\min}(k, \omega) > 1 \]  \hspace{1cm} (7.243)

where \( F_{\min} \) is determined by \( \partial F / \partial \omega = 0 \) from (7.242). We find

\[ \omega_{\min} \equiv \left( \frac{m_e}{m_i} \right)^{1/3} kV_0 \]  \hspace{1cm} (7.244)

and

\[ F_{\min} \equiv \frac{\omega_i^2}{(m_e/m_i)^{2/3} k^2V_0^2} + \frac{\omega_e^2}{k^2V_0^2} \]  \hspace{1cm} (7.245)

which satisfies (7.243) and predicts instability whenever

\[ |kV_0| \gtrsim \omega_e \]  \hspace{1cm} (7.246)

Thus, there is a broad range \(-\omega_e/V_0 < k < \omega_e/V_0\) of unstable wave numbers.

Two-stream instabilities are very common in plasma physics. They happen whenever one fairly cold plasma component has a relative velocity with respect to another plasma component. These components need not be of different species; a cold electron beam impinging on an existing electron–ion plasma will produce its own instability. These instabilities are nature’s way of saying that Maxwellians are desirable, and any configuration that is too far from Maxwellian will not last forever, even in the absence of collisions.

The linear theories of streaming instabilities for both cold components (fluid theory) and warm components (Vlasov theory) are very well understood. The

![Graphical solution of (7.237), for wave numbers k that yield four real roots.](image-url)
nonlinear saturation of these instabilities, involving such concepts as particle orbit modification, nonlinear wave-wave interactions, and strong turbulence, are not so well understood, and are the subject of considerable current research.

Up to this point in our study of the fluid theory, the waves and instabilities have propagated in a spatially homogeneous plasma. In the next section, we consider waves that propagate in a spatially inhomogeneous plasma.

7.14 DRIFT WAVES

Spatial inhomogeneities can give rise to their own wave motions. Consider an electrostatic wave, with frequency high enough that ions are unperturbed, but low enough that electrons perform an $\mathbf{E} \times \mathbf{B}_0$ drift in the wave field (Fig. 7.25). The wave number is predominantly in the $\hat{j}$-direction, but has a small $\hat{k}$ component to allow electrons to flow freely along the field lines. With $\mathbf{E}_i = E_j \hat{j} + E_z \hat{k}$, the $E_j \hat{j} \times \mathbf{B}_0 \hat{k}$ drift is in the $\hat{x}$-direction, causing a charge separation. The continuity equation is

$$\partial_t n + \nabla \cdot (n V) = 0$$  \hspace{1cm} \text{(7.247)}$$

or

$$-i \omega n_i + \partial_a n_0 V_{1a} = 0$$  \hspace{1cm} \text{(7.248)}$$

Fig. 7.25 Vector orientations for an electrostatic drift wave.
where we assume $V_{1x}$ is not a function of $x$, we ignore the $k_z V_{1z}$ term because $k_z$ is small, and we ignore the $k_y V_{1y}$ term because $V_{1y}$ is small, being mostly a result of a polarization drift. Since $V_{1x}$ results primarily from the $E \times B$ drift, we have

$$V_{1x} = \frac{E_1 c}{B_0}$$  \hfill (7.249)

since $E_y = E_1$; thus (7.248) yields

$$n_1 = \frac{1}{i \omega} \frac{\partial n_0}{\partial x} \frac{E_1}{B_0} c$$  \hfill (7.250)

Now the force equation in the $z$-direction, ignoring $-i \omega m_e n_0 V_{1z}$ because of the smallness of $\omega$, is

$$0 = -T_e i k_z n_1 - e n_0 E_z$$

$$= -T_e i k_z n_1 - e n_0 E_1 (k_z/k_y)$$  \hfill (7.251)

or

$$n_1 = \frac{i e n_0 E_1}{T_e k_y}$$  \hfill (7.252)

or equating (7.250) and (7.252) and eliminating $E_1$,

$$\omega = -\frac{T_e k_e}{e n_0} \frac{\partial n_0}{\partial x} \frac{c}{B_0} = \frac{v_e^2}{|\Omega_e| L_n} k_y$$  \hfill (7.253)

where the density scale length

$$L_n \equiv -\left(\frac{1}{n_0} \frac{\partial n_0}{\partial x}\right)^{-1} > 0$$  \hfill (7.254)

Defining the electron diamagnetic drift speed (see Chapter 2)

$$v_{De} = \frac{v_e^2}{|\Omega_e| L_n}$$  \hfill (7.255)

we can write (7.253) in the form

$$\omega = k_y v_{De}$$  \hfill (7.256)

which is the dispersion relation for electrostatic drift waves.

There is a whole zoo of drift waves, matching in diversity all of the waves in homogeneous magnetized plasma. Drift waves are very important in magnetic confinement devices for controlled fusion such as the tokomak and mirror machine, and in the study of planetary ionospheres and magnetospheres. They are discussed in greater detail in Refs. [3], [6], and [8] to [19].

This brings us to the end of our study of linear fluid waves in magnetized and unmagnetized, homogeneous and inhomogeneous plasma. In the next two sections, we introduce the important subject of nonlinear fluid waves by adding one nonlinear term to two of the most important waves in plasma physics: ion-acoustic waves and Langmuir waves.
7.15 NONLINEAR ION-ACOUSTIC WAVES—KORTEweg-DeVRIEES EQUATION

Up to this point in the fluid theory we have considered only linear waves. We must always remember that the theory of linear waves restricts us to very small amplitudes. A wave with a finite amplitude will be susceptible to nonlinear effects, which show up mathematically as products of first order terms. This section and the next section are intended to introduce the concept of nonlinear wave equations and their corresponding solutions, which often take the form of solitons and shock waves.

Here we consider an example of one nonlinear wave equation, the Korteweg-deVries equation [20]:

\[
\partial_t v + v \partial_x v + \alpha \partial_x^3 v = 0
\]  
(7.257)

This equation is obtained by adding one nonlinear term in the derivation of the ion-acoustic wave equation.

Although it is possible to give a rigorous derivation of (7.257), we give here only a heuristic derivation that indicates how one might arrive at (7.257). The origin of the terms in (7.257) is fairly easy to see. The first two terms might arise from the total time derivative of the ion fluid velocity. The third term can be seen in the ion-acoustic dispersion relation (7.104), which upon taking \( T_i = 0, \gamma_e = 1 \), is

\[
\omega^2 = \frac{k^2 c_s^2}{1 + k^2 \lambda_e^2}
\]  
(7.258)

The square root of (7.258) is, for small \( k \lambda_e \),

\[
\omega = \frac{kc_s}{(1 + k^2 \lambda_e^2)^{1/2}} = kc_s \left( 1 - \frac{k^2 \lambda_e^2}{2} \right)
\]  
(7.259)

If we now multiply (7.259) on the right by the ion fluid velocity \( v \), and identify \( -i \omega \) with \( \partial_t \) and \( ik \) with \( \partial_x \), we obtain

\[
\frac{\partial v}{\partial t} = -c_s \frac{\partial v}{\partial x} - c_s \lambda_e^2 \frac{\partial^3 v}{\partial x^3}
\]  
(7.260)

In a frame \( x' = x - c_s t \) moving with the velocity \( c_s \), and defining \( \alpha = c_s \lambda_e^2/2 \), we obtain

\[
\partial_{x'} v + \alpha \partial_{x'}^3 v = 0
\]  
(7.261)

which are the linear terms in (7.257). The nonlinear term is obtained by replacing the partial time derivative \( \partial_t \) with the convective time derivative \( \partial_t + v \partial_x \).

We begin our heuristic derivation with the five fluid equations. Taking \( T_i \to 0 \) so that we can neglect ion pressure in the ion force equation, and taking \( m_e \to 0 \) so that we can neglect electron inertia in the electron force equation, we find

\[
\partial_t n_e + \partial_x (n_e V_e) = 0
\]  
(7.262)

\[
0 = -T_e \partial_x n_e - e n_e E
\]  
(7.263)

\[
\partial_t n_i + \partial_x (n_i V_i) = 0
\]  
(7.264)

\[
m_e n_i \partial_x V_i + m_i n_i V_i \partial_x V_i = e n_e E
\]  
(7.265)

and

\[
\partial_x E = 4 \pi e (n_i - n_e)
\]  
(7.266)
where we have chosen $\gamma_e = 1$. We next linearize (7.262) to (7.266) everywhere except one place: we keep one nonlinear term, the $m_i n_0 V_e \partial_x V_e$ term on the left side of (7.265). We have then

\[
\begin{align*}
\partial_t n_{e1} + n_0 \partial_x V_e &= 0 \quad (7.267) \\
0 &= -T_e \partial_x n_{e1} - en_0 E \quad (7.268) \\
\partial_t n_{i1} + n_0 \partial_x V_i &= 0 \quad (7.269) \\
m_i n_0 \partial_x V_i + m_i n_0 V_i \partial_x V_i &= en_0 E \quad (7.270) \\
\partial_x E &= 4\pi e(n_{i1} - n_{e1}) \quad (7.271)
\end{align*}
\]

**EXERCISE** Can you find seven other nonlinear terms neglected in going from (7.262)–(7.266) to (7.267)–(7.271)?

A more rigorous derivation would show us the regime of validity implied by our neglect of seven other nonlinear terms while retaining only one nonlinear term. It turns out that this regime is reasonably large.

We next assume a plane wave solution, everywhere except in (7.270). [What would happen if we tried to assume a plane wave solution $\sim \exp(-i\omega t + ikx)$ in (7.270)?] We also take $v \equiv V_e \approx V_i$, which means that (7.267) and (7.269) have the same information; we retain the difference between $n_{e1}$ and $n_{i1}$ so that (7.271) can be used. Solving (7.268) for $n_{e1}$, we find

\[
n_{e1} = -\frac{en_0 E}{ikT_e} \quad (7.272)
\]

which inserted in Poisson’s equation (7.271) yields

\[
E = \frac{4\pi en_{i1}}{ik - (\omega^2 m_i / ikT_e)} \quad (7.273)
\]

$n_{i1}$ is from (7.269)

\[
n_{i1} = \frac{k n_0}{\omega} v \quad (7.274)
\]

Both (7.274) in (7.273) and the result in (7.270) yield

\[
\partial_t v + v \partial_x v = -\frac{ik^2 c_i^2}{\omega} (1 + k^2 \lambda_e^2)^{-1/2} v \quad (7.275)
\]

Here, we are still treating the right side as linear; therefore $\omega$ and $k$ have their meanings as differential operators, while the left side is nonlinear. It proves convenient to eliminate $\omega$ on the right side; we do this by using the linear ion-acoustic dispersion relation (7.258), which is obtained from (7.275) by ignoring the nonlinear term and replacing the left side with $-i\omega v$. Solving for $\omega$ and substituting in the right side of (7.275), we have

\[
\partial_t v + v \partial_x v = -ikc_i(1 + k^2 \lambda_e^2)^{-1/2} v \quad (7.276)
\]

For small $k \lambda_e$, we can expand the right side of (7.276) to obtain

\[
\partial_t v + v \partial_x v = -ikc_i(1 - \frac{1}{2} k^2 \lambda_e^2) v \quad (7.277)
\]
Reinterpreting $ik$ as $\partial_x$, this becomes

$$\hat{\partial}_t u + (c_s + v) \hat{\partial}_x u + \alpha \hat{\partial}_x^3 u = 0$$ (7.278)

where $\alpha = \lambda_s^2 c_s / 2$. In the frame $z = x - c_s t$, this is the Korteweg-deVries equation (7.257).

**EXERCISE** Show the above relationship.

Recall that $u(x,t)$ represents fluid velocity in the laboratory frame; this identification of $u(x,t)$ remains true even if we transform to a moving frame. What physics do the various terms in (7.278) represent? The first two terms by themselves,

$$\hat{\partial}_t u + c_s \hat{\partial}_x u = 0$$ (7.279)

merely represent our old ion-acoustic waves in the limit $k \lambda_s \to 0$. The solution of (7.279) is simply a dispersionless wave, $\omega = kc_s$, with phase velocity $V_p \equiv \omega / k = c_s$, and group velocity $d\omega / dk = c_s$ a constant independent of $k$. Suppose we add the nonlinear term to obtain

$$\hat{\partial}_t u + (c_s + v) \hat{\partial}_x u = 0$$ (7.280)

The effect of the nonlinear term is as follows. Consider an initial waveform as shown in Fig. 7.26. As the wave moves, the part with larger $u$ moves faster, so that it overtakes the part with smaller $u$. Eventually, at $t = t_2$, there is an infinite slope, and at $t = t_3$, the wave has broken. Now suppose we had included the dispersive term in (7.278); the term $\alpha \hat{\partial}_x^3 u$ is called dispersive because it contributes a term $k^3$ to the linear dispersion relation $\omega = kc_s - \alpha k^3$; then $V_g \equiv d\omega / dk = c_s - 3\alpha k^2$, which depends on $k$, making this a dispersive wave. We know the effect of dispersion on a wave; it makes a wave packet spread out as it travels. This is just opposite to the steepening observed in the figure. Consider the time between $t = t_1$ and $t = t_2$. Here, the slope is becoming very large. A large slope corresponds to a large $x$-derivative, which makes the $\alpha \hat{\partial}_x^3 u$ term in (7.278) become large. Since we know that the effect of this $\alpha \hat{\partial}_x^3 u$ term is to spread out the wave, we might expect that there could be a balance between the nonlinear steepening and the linear dispersion. Indeed this is the case. One can obtain nonlinear wave packets, known as *solitons*, which travel without change of shape (Fig. 7.27). The physical basis for these solitons involves a balance between dispersion and nonlinearity.

![Fig. 7.26 Effect of the nonlinear term in (7.282).](image-url)
Let us proceed to find a soliton solution to the Korteweg-deVries equation (7.278). We look for stationary solutions in a moving frame,

\[ x' = x - v_0 t \]
\[ t' = t \]

so that

\[ \partial_x = \frac{\partial x'}{\partial x} \partial_{x'} + \frac{\partial x}{\partial x} \partial_{t'} = \partial_{x'} \]

and

\[ \partial_{t'} = \frac{\partial x'}{\partial t} \partial_{x'} + \frac{\partial t'}{\partial t} \partial_{t'} = \partial_{t'} - v_0 \partial_{x'} \]

(7.283)

(7.284)

Since stationary implies \( \partial_{t'} = 0 \), the Korteweg-deVries equation (7.278) becomes

\[ (-v_0 + c_s + u) \partial_{x'} v + \alpha \partial_{x'}^3 v = 0 \]

(7.285)

Remember that \( u(x', t') \) is still that function of space and time which represents the fluid velocity in the lab frame. Equation (7.285) can be integrated once immediately, to give

\[ (c_s - v_0) v + \frac{v^2}{2} + \alpha v'' = 0 \]

(7.286)

where \( (\quad)' \equiv \partial_{x'}(\quad) \) and we have taken the integration constant to vanish. Equation (7.286) is in the form

\[ \alpha v'' = (v_0 - c_s) v - \frac{v^2}{2} \]

(7.287)

which has the same mathematical form as Newton's law of motion,

\[ m \ddot{x} = F(x) = - \partial_x V(x) \]

(7.288)

where \( V(x) \) is the potential energy. Thus, (7.287) has the form

\[ \alpha v'' = - \partial_x \left[ (c_s - v_0) - \frac{v^2}{2} + \frac{v^3}{6} \right] \]

(7.289)

Equation (7.289) has the same mathematical form as a force equation for a particle of mass \( \alpha \) moving under the influence of a potential field given by the quantity in brackets. We call the quantity in brackets the pseudopotential,

\[ \Phi(v) = (c_s - v_0) - \frac{v^2}{2} + \frac{v^3}{6} \]

(7.290)

A graph of \( \phi(v) \) is shown for \( c_s - v_0 > 0 \) in Fig. 7.28. A similar graph of the pseudopotential \( \Phi(v) \) for \( (c_s - v_0) < 0 \) is shown in Fig. 7.29. Only the second form is suitable for our purposes. This is because we desire a localized wave form, \( u(x' \rightarrow \pm \infty) \rightarrow 0 \). This will occur in Fig. 7.29 when the pseudoparticle leaves \( v = 0 \) when the pseudotime \( x' \rightarrow -\infty \), falling once through the well to reach \( v_{\text{max}} \)
at \( x' = 0 \), and taking an infinite amount of pseudotime \( x' \) to fall back through the well to reach \( v = 0 \) as the pseudotime \( x' \to +\infty \). We thus obtain the shape shown in Fig. 7.30. The pseudopotential in Fig. 7.28 would not allow \( v(x' \to \pm \infty) \to 0 \).

Let us now solve (7.287) exactly, with \( c_i - v_0 < 0 \) or \( v_0 > c_s \). We all know how to solve force equations of the form (7.287). Multiply (7.287) by \( v' \) and integrate, to obtain,

\[
\frac{\alpha}{2} (v')^2 = (v_0 - c_s) \frac{v^2}{2} - \frac{v^3}{6}
\]

where we have chosen the constant of integration to be zero because we want \( v' = 0 \) when \( v = 0 \) (Fig. 7.30). Then

\[
\frac{dv}{dx'} = v' = \left( \frac{2}{\alpha} \right)^{1/2} \left[ (v_0 - c_s) \frac{v^2}{2} - \frac{v^3}{6} \right]^{1/2}
\]

or

\[
\frac{dv}{\left[ (v_0 - c_s) \frac{v^2}{2} - \frac{v^3}{6} \right]^{1/2}} = \left( \frac{2}{\alpha} \right)^{1/2} dx'
\]

Each side of (7.293) can be integrated. The left side is of the form

\[
I = \int \frac{dv}{\sqrt{v^2 - \beta v^3}} = \int \frac{dv}{v \sqrt{1 - \beta v}}
\]

where \( \beta = 1/[3(v_0 - c_s)] \). Let \( u = \sqrt{1 - \beta v} \), then \( v = (1 - u^2)/\beta \) and \( du = (-\beta du/2)/\sqrt{1 - \beta v} \). We find

\[
\Phi(v)
\]

Fig. 7.29 Sketch of pseudopotential when \( c_i < v_0 \).
\[ I = -2 \int \frac{du}{1 - u^2} = -\int du \left( \frac{1}{1 - u} + \frac{1}{1 + u} \right) = \ln \left( \frac{1 - u}{1 + u} \right) \] (7.295)

Then
\[ \left( \frac{2}{v_0 - c_s} \right)^{1/2} \ln \left( \frac{1 - u}{1 + u} \right) = \left( \frac{2}{\alpha'} \right)^{1/2} x' \] (7.296)

from (7.293). With \( \gamma \equiv \left[ (v_0 - c_s)/\alpha' \right]^{1/2} \), and exponentiating both sides, we get
\[ \frac{1 - u}{1 + u} = e^{\gamma x'} \] (7.297)

Then \( 1 - u = (1 + u)e^{\gamma x'} \), implying that
\[ u = \frac{1 - e^{\gamma x'}}{1 + e^{\gamma x'}} \] (7.298)

and \( v = (1 - u^2)/\beta \) is
\[ v = \frac{1}{\beta} \left[ \frac{(1 + e^{\gamma x'})^2 - (1 - e^{\gamma x'})^2}{(1 + e^{\gamma x'})^2} \right] = \frac{1}{\beta} \left[ \frac{4e^{\gamma x'}}{(1 + e^{\gamma x'})^2} \right] \] (7.299)

or
\[ v = \frac{1}{\beta} \frac{4}{(e^{\gamma x'/2} + e^{-\gamma x'/2})^2} = \frac{1}{\beta} \text{sech}^2(\gamma x'/2) \] (7.300)

which is
\[ v = 3(v_0 - c_s) \text{sech}^2 \left[ \left( \frac{v_0 - c_s}{4\alpha} \right)^{1/2} x' \right] \] (7.301)

In fact, this solution has only been derived for \( x' < 0 \) since we chose \( v' > 0 \) branch in (7.292); nevertheless, it would be easy to obtain the part of (7.301) for \( x' > 0 \) by choosing the \( v' < 0 \) branch in (7.292); therefore, (7.301) applies to all \( x' \) and is the soliton solution. Note that the larger amplitude solitons are more sharply peaked, having a smaller scale length. This behavior is in accordance with our picture of nonlinearity \( \nu \partial_x \nu \) which balances dispersion \( \partial_x^3 \nu \) (Fig. 7.31). Back in the lab frame, where \( x = x' + v_0 t \), this solution is
\[ v(x,t) = 3(v_0 - c_s) \text{sech}^2 \left[ \left( \frac{v_0 - c_s}{4\alpha} \right)^{1/2} (x - v_0 t) \right] \] (7.302)
**EXERCISE** Write out $\text{sech}^2(x')$ in terms of exponentials, and show that it reproduces the soliton behavior shown in Fig. 7.31.

### 7.16 NONLINEAR LANGMIUR WAVES—ZAKHAROV EQUATIONS

In the previous section, the addition of one nonlinear term to the equation for ion-acoustic waves led to a nonlinear wave equation with soliton solutions. In this section, the addition of a different nonlinear term, representing the ponderomotive force, to the equation for ion-acoustic waves leads to a set of coupled nonlinear wave equations that describe the nonlinear interaction between high frequency Langmuir waves and low frequency ion-acoustic waves.

Consider a collection of linear Langmuir waves in one spatial dimension whose electric field (the subscript $h$ stands for high frequency) can be written

$$E_h(x,t) = \frac{1}{2} \tilde{E}(x,t) \exp(-i\omega_h t) + \text{c.c.} \quad (7.303)$$

The amplitude $\tilde{E}(x,t)$ contains the $\frac{1}{2}k^2\lambda_e^2\omega_e$ frequency dependence of the Langmuir waves. Since $k^2\lambda_e^2 \ll 1$ for Langmuir waves, the function $\tilde{E}(x,t)$ varies slowly in time compared to the rapidly varying $\exp(-i\omega_h t)$. Thus, in the ponderomotive force equation (2.76) the constant field $E_0$ can be replaced by the slowly varying amplitude $\tilde{E}(x,t)$ so that the low frequency ponderomotive force acting on electrons is

$$F_p = \frac{-e^2}{4m_e\omega_e^2} \frac{d}{dx} |\tilde{E}|^2 \quad (7.304)$$

where the plasma frequency $\omega_p$ appears in the denominator because all components of the Langmuir wave field $E_h$ have frequency near the plasma frequency.

Our goal is to rederive the ion-acoustic wave equation including the ponderomotive force (7.304). This couples the low frequency ion-acoustic waves to the high frequency Langmuir waves. If we then rederive the high frequency Langmuir-wave equation including the change in the background density due to the presence of ion-acoustic waves, we will have two coupled nonlinear equations in the two unknowns representing Langmuir-wave electric field and ion-acoustic wave density perturbation.
The derivation of these equations makes explicit use of the fact that the problem has two time scales. Thus, we shall often encounter equations of the general form
\[ a(t) + b(t) \exp (-i\omega t) = c(t) + d(t) \exp (-i\omega t) \]  
(7.305)
where \( a, b, c, \) and \( d \) vary slowly compared to the time scale \( \omega_c^{-1} \), that is,
\[ \left| \frac{1}{a} \frac{da}{dt} \right| \frac{1}{\omega_c} << 1 \]  
(7.306)
and likewise for \( b, c, \) and \( d \). Then to a good approximation we can hold \( a, b, c, \) and \( d \) constant over the short time interval \( 2\pi/\omega_c \) and integrate (7.305) from any time \( t \) to \( t + 2\pi/\omega_c \); the exponential terms vanish leaving
\[ a(t) = c(t) \]  
(7.307)
This procedure is called averaging over the fast time scale. Similarly, one can first multiply (7.305) by \( \exp (i\omega t) \); averaging over the fast time scale then yields
\[ b(t) = d(t) \]  
(7.308)
In this manner, one can pick out all of the terms in a given equation that have either a fast or a slow time dependence. Similar considerations apply to terms with different wave numbers.

With these preliminaries, let us derive a unified set of fluid equations that describes Langmuir-wave physics, ion-acoustic wave physics, and the nonlinear coupling between them. The discussion is heuristic; we keep only the nonlinear terms we are looking for and throw away many others without rigorous justification. All quantities are separated into high frequency (subscript \( h \)) and low frequency (subscript \( l \)) components,
\[ n_e(x,t) = n_0 + n_{el}(x,t) + n_{eh}(x,t) \]  
(7.309)
\[ n_i(x,t) = n_0 + n_{il}(x,t) \]  
(7.310)
\[ V_e(x,t) = V_{el}(x,t) + V_{eh}(x,t) \]  
(7.311)
\[ V_i(x,t) = V_{il}(x,t) \]  
(7.312)
\[ E(x,t) = E_{el}(x,t) + E_{eh}(x,t) \]  
(7.313)
where we ignore the high frequency portions of ion quantities because of their large mass. The density perturbations \( n_{el}, n_{eh}, \) and \( n_{il} \) are all considered to be much smaller than \( n_0 \).

First, we repeat the derivation of the Langmuir-wave equation including the density perturbation \( n_{el}(x,t) \) due to the low frequency waves. The high frequency components of Poisson’s equation, the electron continuity equation, and the electron force equation are
\[ \partial_x E_h = -4\pi e n_{eh} \]  
(7.314)
\[ \partial_t n_{el} + \partial_x [n_0 + n_{el}] V_{eh} = 0 \]  
(7.315)
\[ m_e n_0 \partial_t V_{eh} = -3T_e \partial_x n_{eh} - en_0 E_h \]  
(7.316)
where we note that the product of a high frequency term and a low frequency term is a high frequency term. The total low frequency electron density \( n_0 + n_{el} \) has been replaced by \( n_0 \) in several places in (7.315) and (7.316), and the term \( \partial_x (n_{eh} V_{el}) \) has been ignored in (7.315). Taking the time derivative of only the high frequency
terms in (7.315), eliminating \( \partial_t V_{eh} \) using (7.316), and eliminating \( n_{eh} \) using (7.314) yield

\[
\partial_t^2 E_h + \omega_e^2 E_h - 3v_e^2 \partial_x^2 E_h = - \omega_e^2 \frac{n_{el}}{n_0} E_h
\]

(7.317)

where \( \omega_e^2 \equiv 4\pi n_0 e^2/m_e \). The left side is easily recognizable as the linear Langmuir-wave equation, while the right side gives the change in the effective plasma frequency due to the fact that the low frequency electron density is \( n_0 + n_{el} \) rather than \( n_0 \).

Inserting the form (7.303) into (7.317) and keeping only terms with time dependence \( \exp(-i\omega_1 t) \), we find

\[
i \partial_t \vec{E} + \frac{3}{2} \frac{v_e^2}{\omega_e} \partial_x^2 \vec{E} = \frac{\omega_e}{2} \frac{n_{el}}{n_0} \vec{E}
\]

(7.318)

where the term \( |\partial_x^2 \vec{E}| \ll |\omega_e \partial_t \vec{E}| \) has been discarded. Equation (7.318) is now a low frequency equation describing the time evolution of the slowly varying envelope \( \vec{E}(x, t) \) of the rapidly varying electric field \( E_h(x, t) \).

Next, we repeat the derivation of the ion-acoustic wave equation including the ponderomotive force (7.304) in the electron force equation. Assuming quasineutrality \( n_{el} \approx n_d \) and \( V_{el} \approx V_{it} \), the low frequency part of the electron continuity equation is

\[
\partial_t n_{el} + n_0 \partial_x V_{el} = 0
\]

(7.319)

where the term \( \partial_x(n_{el} V_{el}) \) has been ignored; the low frequency part of the electron force equation, ignoring \( m_e \partial_x V_{el} \) because of the small electron mass, is

\[
0 = -\frac{T_e \gamma_e}{n_0} \partial_x n_{el} - eE_i - \frac{e^2}{4m_e \omega_e^2} \partial_x |\vec{E}|^2
\]

(7.320)

and the ion force equation yields

\[
m_i \partial_x V_{el} = -\frac{T_i \gamma_i}{n_0} \partial_x n_{el} + eE_i
\]

(7.321)

Here, \( \gamma_e \) and \( \gamma_i \) are the usual factors relating pressure change to density change, and \( n_0 + n_d \) has been replaced by \( n_0 \) in several places in (7.320) and (7.321).

Solving (7.321) for \( E_i \), substituting the result in (7.320), taking the spatial derivative, and eliminating \( V_{el} \) using (7.319), yield

\[
\partial_t^2 n_{el} - c_e^2 \partial_x^2 n_{el} = \frac{1}{16\pi m_i} \partial_x^2 |\vec{E}|^2
\]

(7.322)

where the sound speed is defined by

\[
c_e^2 = \frac{\gamma_e T_e + \gamma_i T_i}{m_i}
\]

(7.323)

as usual. The coupled equations (7.318) and (7.322) were first derived by Zakharov [21] and are known as the Zakharov equations.
We wish to study the consequences of the nonlinear equations (7.318) and (7.322), including soliton solutions and parametric instabilities. It is convenient to define dimensionless variables as

\[
\eta = \frac{\gamma_e T_e + \gamma_i T_i}{T_e},
\]

(7.324)

\[
\tau = \left( \frac{2\eta}{3} \right) \left( \frac{m_e}{m_i} \right) (\omega_e t)
\]

(7.325)

\[
z = \left( \frac{2}{3} \right) \left( \frac{\eta m_e}{m_i} \right)^{1/2} \left( \frac{x}{\Lambda_e} \right)
\]

(7.326)

\[
E \equiv \left( \frac{1}{\eta} \right) \left( \frac{m_i}{m_e} \right)^{1/2} \left( \frac{3E^2}{64\pi n_0 T_e} \right)^{1/2}
\]

(7.327)

\[
n = \left( \frac{3m_i}{4\eta m_e} \right) \left( \frac{n_{e}}{n_0} \right)
\]

(7.328)

whereupon (7.318) and (7.322) become

\[
i \frac{\partial}{\partial z} E + \frac{\partial^2}{\partial z^2} E = nE
\]

(7.329)

\[
\frac{\partial}{\partial t} n - \frac{\partial^2}{\partial z^2} n = \frac{\partial^2}{\partial z^2} |E|^2
\]

(7.330)

Let us look for soliton solutions to (7.329) and (7.330). The simplest soliton solution [22] is one that is stationary in the laboratory frame; it is a bump of electric field intensity that exists self-consistently with the hole in ion density dug out by the ponderomotive force. The first term on the left of (7.330) vanishes; integrating twice and setting the constants of integration equal to zero yield

\[
n = - |E|^2
\]

(7.331)

so that (7.329) becomes

\[
i \frac{\partial}{\partial z} E + \frac{\partial^2}{\partial z^2} E + |E|^2 E = 0
\]

(7.332)

which is called the nonlinear Schrödinger equation because it resembles the quantum mechanical Schrödinger equation.

Looking for a solution of the form

\[
E(z, \tau) = \exp(i\Omega \tau) f(z)
\]

(7.333)

we find that Eq. (7.332) becomes [with \((\ )' \equiv d(\ )/dz] \n
\[
f'' = \Omega f - f^3
\]

(7.334)

This can be solved by the same pseudopotential method used in the previous section to solve the Korteweg-deVries equation. We write (7.334) in the form

\[
f'' = - \frac{d}{df} \left[ \frac{1}{4} f^4 - \frac{1}{2} \Omega f^2 \right]
\]

(7.335)

Multiplying both sides by \(f'\) and integrating yield

\[
(f')^2 = \Omega f^2 - \frac{1}{2} f^4
\]

(7.336)
or

\[ \frac{df}{dz} = f \left( \Omega - \frac{1}{2} f^2 \right)^{1/2} \]  

(7.337)

or

\[ \frac{df}{f \left( \Omega - \frac{1}{2} f^2 \right)^{1/2}} = dz \]  

(7.338)

or

\[ \int \frac{df}{f \left( \Omega - \frac{1}{2} f^2 \right)^{1/2}} = z \]  

(7.339)

This integral can be performed with the substitution \( u = \left( 1 - f^2 / 2\Omega \right)^{1/2} \). With \( f > 0 \) everywhere, (7.339) can be integrated to yield

\[ \frac{1}{2} \ln \left( \frac{1 - u}{1 + u} \right) = \Omega^{1/2} z \]  

(7.340)

Solving for \( u \) and converting back to \( f \), one finds

\[ f = (2\Omega)^{1/2} \text{sech} (\Omega^{1/2} z) \]  

(7.341)

so that the total field, as given by (7.333), is

\[ E(z, \tau) = (2\Omega)^{1/2} \exp (i\Omega \tau) \text{sech} (\Omega^{1/2} z) \]  

(7.342)

which can be called a *Langmuir soliton*.

**EXERCISE** Sketch the solution (7.342) and show that it is indeed a localized “bump.” Sketch the density perturbation (7.331).

A more general class of solitons exists [23], moving at any speed the absolute value of which is less than the sound speed.

In the next section, we turn our attention to another important subject that can be studied within the context of the Zakharov equations: *parametric instabilities*. The study of solitons and parametric instabilities is one of the most active areas of research in plasma physics [24–26].

### 7.17 PARAMETRIC INSTABILITIES

Consider a plasma that contains a single plane wave of finite amplitude. Within the fluid theory, the system of plasma plus wave can be thought of as a time-dependent equilibrium state. We can then ask the question: Is such an equilibrium stable or unstable? This is the same question we asked about time-independent equilibria in Chapter 6 on Vlasov theory and in Section 7.13 on the two-stream instability. The answer to the question often indicates instability, and such instabilities are called *parametric instabilities*, the “parameter” being the amplitude of the single wave.
One can look for such instabilities with any of the waves studied in this book. For example, we shall use Langmuir waves, the stability of which can be studied within the context of the Zakharov equations of the previous section. It turns out that the most general instability in this case involves the single finite-amplitude Langmuir wave, two other Langmuir waves, and one low frequency wave. The stability analysis proceeds by assuming that the amplitudes of the two other Langmuir waves and the low frequency wave are infinitesimal. We choose

$$E(z, \tau) = E_0 \exp(-i\omega_0 \tau + ik_0 z) + E_+ \exp[-i(\omega_0 + \omega)\tau + i(k_0 + k)z] + E_- \exp[-i(\omega_0 - \omega)\tau + i(k_0 - k)z]$$

(7.343)

and

$$n = \bar{n} \exp(-i\omega \tau + ikz) + \text{complex conjugate}$$

(7.344)

where $\bar{n}$, $E_+$, and $E_-$ are all much smaller than $E_0$. The equilibrium solution $E(z, \tau) = E_0 \exp(-i\omega_0 \tau + ik_0 z)$, $n(z, \tau) = 0$, is chosen to satisfy the Zakharov equations with $E_0$ real.

**EXERCISE** Show that this solution implies $\omega_0 = k_0^2$.

Inserting the forms (7.343) and (7.344) into the first Zakharov equation (7.329), and keeping only those terms with spatial dependence $i\exp[i(k_0 + k)z]$, we find

$$\omega_0 + \omega E_+ - (k_0 + k)^2 E_+ = \bar{n}E_0$$

(7.345)

Likewise, the terms with spatial dependence $i\exp[i(k_0 - k)z]$ yield

$$\omega_0 - \omega E_- - (k_0 - k)^2 E_- = \bar{n}^*E_0$$

(7.346)

Solving (7.345) and (7.346) for $E_+$ and $E_-$, inserting these into the second Zakharov equation (7.330), keeping only terms with spatial variation $i\exp(ikz)$, and eliminating $\bar{n}$ from each term yield the dispersion relation

$$\omega^2 - k^2 = k^2 E_0^2 \left( \frac{1}{\omega - k^2 - 2k_0 k} + \frac{1}{\omega - k^2 + 2k_0 k} \right)$$

(7.347)

There are several types of solutions. With $k_0 > 0$, we first look for an instability with $k < 0$. If $|\omega|$ is small, the second denominator on the right is larger than the first, so we ignore the second. This is equivalent to ignoring the term $E_-$ in the electric field (7.343), so this instability involves only $E_0$, $E_+$, and $\bar{n}$ and is thus known as a three-wave interaction. The dispersion relation is now

$$(\omega^2 - k^2) (\omega - 2kk_0 - k^2) - k^2 E_0^2 = 0$$

(7.348)

Looking for a solution with $\omega = k + \delta$ where $|\delta| \ll |k|$, we write $(\omega^2 - k^2) = (\omega + k)(\omega - k) = (2k + \delta)\delta \approx 2k\delta$; Eq. (7.348) then yields

$$\delta^2 + (2k - 2kk_0 - k^2) - \frac{kE_0^2}{2} = 0$$

(7.349)

At the particular negative wave number that satisfies $k - 2kk_0 - k^2 = 0$ or $k = -2k_0 + 1$, this is
\[ \delta = \pm \left( \frac{kE_0^2}{2} \right)^{1/2} \]  

which indicates instability since \( k < 0 \). If \( k_0 >> 1 \), this becomes

\[ \delta = ik_0^{1/2}E_0 \]  

**EXERCISE** Show that in physical units denoted by a tilde, \( k_0 >> 1 \) means \( \tilde{k}_0 \lambda_e >> (m_e/m_i)^{1/2} \).

**EXERCISE** What does \( |\delta| << |k| \) mean in physical units?

Since the electric field \( E \), has a wave number \( k = k_0 - 2k_0 + 1 = -k_0 + 1 \), \( E \) has a negative wave number and travels in the opposite direction to \( E_0 \). It is known as a *backscatter instability*, and is one example of a *parametric decay instability*. The physical growth rate \( \tilde{\gamma} \) is

\[ \frac{\tilde{\gamma}}{\omega_e} = \left( \frac{m_e}{\eta m_i} \right)^{1/4} \left( \tilde{k}_0 \lambda_e \right)^{1/2} \frac{E_0}{(32\pi n_0 T_e)^{1/2}} \]  

where physical quantities are denoted by a tilde.

**EXERCISE** Demonstrate (7.352) from (7.351).

The dispersion relation (7.347) also yields an instability that involves all of the terms and thus is known as a *four-wave interaction*. The simplest case is when \( \omega_0 = k_0 = 0 \); that is, the physical field represented by \( E_0 \) is oscillating exactly at the plasma frequency \( \omega_e \) and has zero wave number (a so-called *dipole field*). Looking for a purely growing instability \( \omega = i\gamma \), we see that the dispersion relation (7.347) becomes

\[ (\gamma^2 + k^2)(\gamma^2 + k^4) - 2k^4 E_0^2 = 0 \]  

the solution of which is

\[ \gamma^2 = -\frac{1}{2} (k^2 + k^4) + \frac{1}{2} \left[ (k^2 - k^4)^2 + 8k^4 E_0^2 \right]^{1/2} \]  

With both \( k << 1 \) and \( E_0 << 1 \) the \( k^6 \) term within the bracket can be discarded, and the square root can be expanded to yield

\[ \gamma = k(2E_0^2 - k^2)^{1/2} \]  

which is the growth rate of the four-wave interaction known as the *oscillating two-stream instability* [27]. The growth rate versus wave number is sketched in Fig. 7.32. The maximum growth rate \( \gamma = E_0^2 \) occurs at \( k = \pm E_0 \).

**EXERCISE** Show that in physical units these are

\[ \frac{\tilde{\gamma}}{\omega_e} = \frac{E_0^2}{32\pi n_0 T_e} \]  

and

\[ \tilde{k}_0 \lambda_e = \left( \frac{E_0^2}{48\pi n_0 T_e} \right)^{1/2} \]
Fluid Equations

Fig. 7.32 Growth rate versus wave number for the oscillating two-stream instability.

The study of parametric instabilities is very important for such fields as laser fusion, particle beam fusion, radio-frequency heating of the ionosphere and of magnetic confinement devices, and solar radio physics.

This brings us to the end of our study of the fluid equations of plasma physics. In the next chapter, the fluid equations for each species are combined to yield the equations of magnetohydrodynamics.

REFERENCES

**PROBLEMS**

7.1 **Energy Transport Equation**

Obtain an equation for the fluid transport of particle kinetic energy by multiplying the Vlasov equation by $\frac{1}{2} m v^2$ and integrating over all velocity space. Simplify your result in any convenient fashion.

7.2 **Fluid Conservation Properties**

Suppose we have an electron-proton plasma that is finite in extent in all three dimensions. Suppose there is no magnetic field. Using the fluid equations, prove that

(a) For each species, total particles are conserved.

(b) Momentum is not necessarily conserved for each species.

(c) Total momentum, summed over species, is conserved.

7.3 **Langmuir Waves**

One does not need to look for individual sinusoidal wave solutions to solve wave equations. Consider the electron fluid equations in the differential form (7.38) to (7.40).

(a) Combine these equations, and linearize, to obtain the linear partial differential wave equation

$$(\partial_t^2 - \omega_e^2 - 3v_e^2 \partial_x^2)E(x,t) = 0$$
Fluid Equations

(b) Suppose the initial conditions for \( E(x,t) \) are

\[
E(x, t = 0) = f(x), \\
\dot{E}(x, t = 0) = 0
\]

where an overdot indicates a time derivative. Using Fourier and Laplace transform techniques, find an exact explicit solution for the time evolution of \( E(x,t) \).

(c) Suppose \( f(x) \) represents a standard wave packet, a sinusoidal variation with space accompanied by a Gaussian envelope

\[
E(x, t = 0) = f(x) = E_0 e^{-x^2/2L^2} \sin k_0 x
\]

where we assume \( k_0 \gg L^{-1} \). By using an appropriate approximation, if necessary, in the exact solution from (b), show that the wave packet travels with the group speed

\[
|V_g| = \left| \frac{d\omega}{dk} \right|_{k = k_0} = |3(k_0 \lambda_e) u_e|
\]

Show also that the packet spreads as it propagates, and the rate of spreading (dispersion) is proportional to \( |dV_g/dk|_{k = k_o} \). Does the packet move to the right, to the left, or does it split into right- and left-going pieces?

7.4 Negative Energy Waves

Suppose a plasma has cold electrons drifting with velocity \( v_0 \) with respect to cold ions. Derive the wave dispersion relation corresponding to high frequency electron plasma waves. Show that if the frame moving with the electrons, these are just our old cold plasma waves. Plot the two branches of \( \omega(k) \) vs. \( k \). Use the wave energy formula (6.72) to evaluate the wave energy. Indicate the regions of your dispersion diagram where the energy is negative.

7.5 Upper Hybrid vs. Right Cutoff Frequency

Prove that the right cutoff frequency

\[
\omega_R = \frac{1}{2} |\Omega_e| + \left[ \omega_e^2 + \left( \Omega_e^2/4 \right) \right]^{1/2}
\]

is always greater than or equal to the upper hybrid frequency

\[
\omega_{UH} = (\omega_e^2 + \Omega_e^2)^{1/2}
\]

7.6 Upper Hybrid Wave

Compare the derivations of the upper hybrid wave (a perpendicular, electrostatic wave) and the extraordinary wave (a perpendicular, partially electromagnetic and partially electrostatic wave). Does the assumed form of the upper hybrid wave satisfy Maxwell's equations? Why not? In which parameter regime does it approximately satisfy Maxwell's equations? In this parameter regime, is there any difference between the upper hybrid wave and the extraordinary wave? In the X-mode derivation, show that Faraday's law contains the same information as would be contained by Poisson's equation plus the electron continuity equation. Reproduce
the graph of \( n \equiv ck/\omega \) for the extraordinary wave and draw the dispersion diagram for the upper hybrid wave. For which portion of each diagram do we trust the derivation? Which portion of the \( X \)-mode diagram corresponds to the upper hybrid wave?

### 7.7 Model of Collisions

We wish to derive a simple model of collisional effects in a plasma. Suppose that a typical particle suffers collisions at a rate \( \nu \). Then the particle when oscillating in the electric field of a wave will occasionally suffer a collision (assuming \( \nu \ll \omega \)) and to the first approximation can be thought to lose all of its directed energy. An electron fluid element with velocity \( v \) will thus lose momentum at a rate \( -\nu n_0 m_e \), where we have assumed that each colliding electron loses momentum \( -m_e v \). Thus, we can add a term in the electron force equation to represent collisions,

\[
\dot{n}_e m_e \nabla_v V_e + n_e m_e \nabla_v V_e \cdot \nabla V_e = -\nabla P_e - e n_e E - \nu n_e m_e V_e
\]

With this extra term, rederive the Langmuir wave dispersion relation, assuming \( \nu \ll \omega \). At what rate does the electric field damp away? At what rate does the wave energy damp away?

### 7.8 Low Frequency Dielectric Constant

Recall that in the theory of dielectrics, one likes to include the currents in

\[
\nabla \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \partial_t \mathbf{E}
\]

in the dielectric function \( \varepsilon \); thus

\[
\nabla \times \mathbf{B} = \frac{1}{c} \partial_t \mathbf{D}
\]

where

---

**Fig. 7.33** Configuration for Problem 7.9.
Fluid Equations

\[ D = \varepsilon E \]

Suppose that a slowly varying sinusoidal electric field is applied across a magnetic field. Derive an expression for \( \varepsilon \) by considering the polarization current produced by the electric field. What do you suppose "slowly varying" means?

7.9 Kunkel's Problem

A plasma of mass density \( \rho = n_o(m_i + m_e) \) is bounded by two parallel conducting plates separated by a distance \( L \). A gravitational acceleration \( g \) is applied at right angles to a uniform magnetic field \( B \), and both of these are parallel to the plates as shown in Fig. 7.33. Show by means of a careful particle drift analysis that the plasma can accelerate freely downward only if switch \( S \) is open, and if the low frequency dielectric function from the previous problem is \( \varepsilon >> 1 \). What is the voltage between the two plates in that case? If \( S \) is closed, what is the current density between the two plates?

7.10 Laser Fusion

In order to obtain controlled thermonuclear fusion using deuterium and tritium, one needs to satisfy the Lawson criterion \( n \tau > 10^{14} \) (c.g.s.) at a temperature \( T \approx 10 \) keV, where \( n \) is the number of particles per cm\(^3\), and \( \tau \) is the confinement time in sec. Use the Lawson criterion to derive the corresponding requirement for laser pellet fusion, \( \rho r > 1 \) (c.g.s.) where \( \rho \) is the density of the compressed pellet in g/cm\(^3\) and \( r \) is the radius of the compressed pellet in cm. (Hint: How does one define "confinement time" for inertial "confinement"? How can one estimate this physically?)
8.1 INTRODUCTION

Chapter 7 is concerned with a set of equations, the fluid equations, which were derived from the Vlasov equation, which in turn was derived from the Klimontovich equation by neglecting all collision effects. Thus, all of the phenomena discussed in Chapter 7 will occur only when collisions are not important. A rough criterion for the importance of collisions is obtained by comparing the collision frequency \( \nu_{ei} \) to the frequency \( \omega \) of the phenomenon under consideration; the fluid treatment is valid when \( \nu_{ei} \ll \omega \). Since we have seen (Section 1.6) that the collision frequency \( \nu_{ei} \approx \omega_o/\Lambda \), there is a huge range of frequencies where the fluid treatment applies. However, there is a significant range of frequencies, \( 0 \leq \omega \leq \nu_{ei} \), where the fluid treatment does not apply. In particular, one often wants to find an equilibrium plasma configuration; for example, in tokamaks, mirror machines, planetary magnetospheres, pulsar magnetospheres, and stellar winds. An equilibrium is equivalent to \( \omega = 0 (\partial_i = 0) \), and collisions must be included in such considerations.

Let us then develop a set of equations that are valid for low frequencies. [Students who have not studied Chapters 3 and 6 can skip directly to (8.3) and (8.7) with the understanding that the extra terms represent the physics of collisions.] Recall the plasma kinetic equation (3.26),

\[
\partial_t f_s + \mathbf{v} \cdot \nabla_x f_s + \left( \frac{q_s}{m_s} \mathbf{E} + \frac{q_s}{m_s} \mathbf{v} \times \mathbf{B} \right) \cdot \nabla_v f_s
\]

\[
= - \frac{q_s}{m_s} \left( \delta \mathbf{E} + \frac{\mathbf{v}}{c} \times \delta \mathbf{B} \right) \cdot \nabla_v \delta N_s \tag{8.1}
\]
Here, \( f_s(x, v, t) \) is a smooth function obtained by averaging the Klimontovich density \( N_s(x, v, t) \) over an appropriate volume, while \( \delta N_s \) is the difference between the smooth function \( f_s \) and \( N_s \), which is the sum of delta functions. In Chapter 3 we argued that the right side represents discrete particle effects, including collisions. We can therefore invent a symbol for the right side of (8.1), \( \frac{\partial f}{\partial t} \), and write (8.1) as

\[
\partial_t f_s + v \cdot \nabla_x f_s + \frac{q_s}{m_s} \left( \frac{v}{c} \times B \right) \cdot \nabla_v f_s = \left( \frac{\partial f_s}{\partial t} \right)_c.
\]  

(8.2)

Thus, we are thinking of \( f_s \) as the number of particles in a small volume of six-dimensional phase space \( (x, v) \), divided by that volume. (See the discussion in Section 6.1.) Then \( \frac{\partial f_s}{\partial t} \) is the rate that particles are gained or lost by that small volume because of collisions. Recall that \( E \) and \( B \) in (8.2) are also averaged quantities, so that they do not include the fields due to individual particles. This identification of \( \frac{\partial f_s}{\partial t} \) is admittedly crude, but we shall not attempt to do better here. There does exist a large body of more exact literature that starts from the formally exact expression (8.1). Here, we use (8.2) to try to obtain the most significant effects of collisions.

Having identified \( \frac{\partial f_s}{\partial t} \), as the change in \( f_s(x, v, t) \) due to collisions, we expect it to have a much stronger influence on the velocity dependence of \( f_s \) than on the spatial dependence of \( f_s \). This is because a collision can cause a huge change in a particle’s velocity, but does not cause much change at all in a particle’s position.

In Section 7.2 we obtained the fluid equations by integrating the Vlasov equation (6.5) over velocity space after multiplying by an appropriate power of velocity. Let us repeat that procedure with (8.2). Multiplying by unity and integrating over all velocity space, we obtain

\[
\partial_t n_s(x, t) + \nabla \cdot (V_s n_s) = \int dv \left( \frac{\partial f_s}{\partial t} \right)_c.
\]

(8.3)

where the left side is as in (7.15). The right side represents the change in the number of particles in a small volume of real space due to collisions; we have just argued that this is very small since collisions do not cause large changes in particle positions; therefore we set this to zero and obtain

\[
\partial_t n_s(x, t) + \nabla \cdot (n_s V_s) = 0
\]

(8.4)

which is just the continuity equation (7.15).

Next, multiply (8.2) by \( v \) and integrate over all velocity space; we obtain the force equation (7.28) with the addition of one term. This is

\[
m_s n_s \partial_t V_s + m_s n_s (V_s \cdot \nabla) V_s = -\nabla P_s + q_s n_s \left( \frac{v}{c} \times B \right) + m_s \int dv v \left( \frac{\partial f_s}{\partial t} \right)_c.
\]

(8.5)

The term

\[
K_s = m_s \int dv v \left( \frac{\partial f_s}{\partial t} \right)_c.
\]

(8.6)
represents the change in the momentum of species \( s \) at position \( x \) due to collisions. A species cannot change its own momentum by colliding with itself; the center of mass of two electrons, for example, is not accelerated during a collision of the two electrons (see Section 2.9). However, the momentum of electrons in a certain volume of space can certainly be changed by collisions with the ions. For example, a beam of electrons incident on a plasma will slow down due to collisions with the ions; the ions begin to move in the initial direction of the electron beam because they have taken up the electron momentum. Thus, we expect \( K_s(x) = -K_e(x) \). It would be possible to develop simple but crude models for \( K_e(x) \), but here we shall leave \( K_s \) in general form. Our force equation then is written as

\[
m_s \rho_s \partial_t V_s + m_s n_s (V_s \cdot \nabla) V_s = -\nabla P_s + q_s n_s (E + \frac{1}{c} V_s \times B) + K_s(x) \quad (8.7)
\]

The fluid equations (8.4) and (8.7) are the same as the fluid equations in Chapter 7, without the term \( K_s(x) \) in (8.7). When written for both electrons and for ions, this set is called the two-fluid model. We now wish to combine the electron equations with the ion equations to obtain a one-fluid model, also known as the equations of magnetohydrodynamics (MHD). We thus wish to think of a single fluid characterized by a mass density

\[
\rho_M(x) \equiv m_i n_i(x) + m_e n_e(x) \approx m_i n_i(x) \quad (8.8)
\]

a charge density

\[
\rho_e(x) \equiv q_e n_i(x) + q_i n_e(x) = e(n_i - n_e) \quad (8.9)
\]

a center of mass fluid flow velocity

\[
V \equiv \frac{1}{\rho_M} (m_i n_i V_i + m_e n_e V_e) \quad (8.10)
\]

a current density

\[
J \equiv q_e n_i V_i + q_i n_e V_e \quad (8.11)
\]

and a total pressure

\[
P \equiv P_e + P_i \quad (8.12)
\]

We wish to derive four equations relating these quantities: a mass conservation equation, a charge conservation equation, a momentum equation, and a generalized Ohm's law.

First we derive a mass conservation law. Multiply the ion continuity equation (8.4) by \( m_i \), the electron continuity equation (8.4) by \( m_e \), and add to obtain

\[
\frac{\partial \rho_M}{\partial t} + \nabla \cdot (\rho_M V) = 0 \quad (8.13)
\]

which is the mass conservation law.

Next, multiply the ion continuity equation (8.4) by \( q_i \), the electron continuity equation (8.4) by \( q_e \), and add to obtain
which is the charge continuity equation or charge conservation law.

Consider next the force equation (8.7). Regarding \(V\), and \(\partial n\), as small quantities, neglecting the products of small quantities, and recalling \(K_e = -K_i\), we add (8.7) for electrons and ions to obtain

\[
\rho_M \frac{\partial V}{\partial t} = -\nabla P + \rho_e e + \frac{1}{c} J \times B
\]

which is the one-fluid force equation, or momentum equation.

Finally, we desire an equation for the time derivative of the current, called a generalized Ohm's law. Multiplying the force equation (8.7) by \(q_e/m_e\), adding the ion version to the electron version, neglecting quadratic terms in the small quantities \(\partial n\) and \(V\), and using \(q_i = -q_e = e\), we find

\[
\frac{\partial J}{\partial t} = \frac{-e}{m_i} \nabla P_i + \frac{e}{m_e} \nabla P_e + \left(\frac{e^2 n_e}{m_e} + \frac{e^2 n_i}{m_i}\right) E + \frac{e^2 n_e}{m_e c} V_e \times B
\]

\[
+ \frac{e^2 n_i}{m_i c} V_i \times B + \left(\frac{e}{m_i} + \frac{e}{m_e}\right) K_i
\]

We notice that

\[
\frac{n_e e^2}{m_e c} V_e = \frac{e}{m_e c} (n_e e V_e - n_e e V_i) + \frac{e^2}{m_e m_i c} (m_i n_i V_i)
\]

\[
= -\frac{e}{m_e c} J + \frac{e^2}{m_e m_i c} (m_i n_i V_i + m_e n_e V_e)
\]

\[
= -\frac{e}{m_e c} J + \frac{e^2}{m_e m_i c} (\rho_M V)
\]

where the first line merely adds and subtracts the same quantity, and the second line adds the tiny quantity \((m_e/m_i)\)\(V_e\), which is negligible compared to \(V_e\) as already incorporated into \(J\).

Using (8.17) in (8.16), neglecting \(m_i^{-1} \ll m_e^{-1}\) wherever possible, and assuming that \(P_e \approx P_i \approx \frac{1}{2} P\) and \(n_i \approx n_e\), we find

\[
\frac{\partial J}{\partial t} = \frac{e}{2m_e} \nabla P + \frac{e^2 \rho_M}{m_e m_i} (E + \frac{1}{c} V \times B) - \frac{e}{m_e c} J \times B + \frac{e}{m_e} K_i
\]

Recall that \(K_i\) represents the change in ion momentum due to collisions with electrons. It is reasonable then to assume that \(K_i\) is a function of the relative velocity \(V_i - V_e\) between the two species; keeping only the first term in a Taylor expansion of \(K_i\), we find

\[
K_i = C_1 (V_i - V_e)
\]

\[
= C_2 J
\]
where the constant $C_2$ has been put in a form such that $\sigma$ can be identified as a conductivity, as we shall see. The minus sign has been chosen because we expect collisions to decrease the current caused by relative species velocity. When we multiply by $m_i m_e / \rho M e^2$, (8.18) becomes

\[
\frac{m_i m_e}{\rho M e^2} \frac{\partial J}{\partial t} = \frac{m_i}{2 \rho M e} \nabla P + E + \frac{1}{c} \mathbf{V} \times \mathbf{B} - \frac{m_i}{\rho M e c} \mathbf{J} \times \mathbf{B} - \frac{J}{\sigma}
\]

(8.20)

which is the **generalized Ohm’s law**. The name comes from the fact that if the only important terms are the second and the fifth terms on the right side, we have

\[
\mathbf{J} = \sigma \mathbf{E}
\]

(8.21)

which is Ohm’s law and in which $\sigma$ is clearly the conductivity.

This completes our derivation of the MHD equations. Collecting these equations, we have

\[
\frac{\partial \rho_M}{\partial t} + \nabla \cdot (\rho_M \mathbf{V}) = 0
\]

(8.13)

\[
\frac{\partial \rho_e}{\partial t} + \nabla \cdot \mathbf{J} = 0
\]

(8.14)

\[
\rho_M \frac{\partial \mathbf{V}}{\partial t} = - \nabla P + \rho_e \mathbf{E} + \frac{1}{c} \mathbf{J} \times \mathbf{B}
\]

(8.15)

\[
\frac{m_i m_e}{\rho M e^2} \frac{\partial \mathbf{J}}{\partial t} = \frac{m_i}{2 \rho M e} \nabla P + \mathbf{E} + \frac{1}{c} \mathbf{V} \times \mathbf{B} - \frac{m_i}{\rho M e c} \mathbf{J} \times \mathbf{B} - \frac{J}{\sigma}
\]

(8.20)

When coupled to Maxwell’s equations

\[
\nabla \times \mathbf{E} = - \frac{1}{c} \frac{\partial \mathbf{B}}{\partial t}
\]

(8.22)

and

\[
\nabla \times \mathbf{B} = \frac{4\pi}{c} \mathbf{J} + \frac{1}{c} \frac{\partial \mathbf{E}}{\partial t}
\]

(8.23)

we have 14 equations in the 14 unknowns $\rho_M, \rho_e, \mathbf{V}, \mathbf{J}, \mathbf{E}$, and $\mathbf{B}$; this assumes that the pressure $P$ can be expressed in terms of the mass density $\rho_M$.

For very low frequencies, one can ignore the $\partial_t \mathbf{J}$ term in the generalized Ohm’s law, whereas for low temperatures the $\nabla P$ term can be ignored. In addition, when the current is small we can neglect the $\mathbf{J} \times \mathbf{B}$ term (known as the Hall term) compared to the $\mathbf{V} \times \mathbf{B}$ term; under all these assumptions, Ohm’s law (8.20) becomes

\[
0 = \mathbf{E} + \frac{1}{c} \mathbf{V} \times \mathbf{B} - \frac{\mathbf{J}}{\sigma}
\]

(8.24)
or
\[ \mathbf{J} = \sigma \left( \mathbf{E} + \frac{1}{c} \mathbf{V} \times \mathbf{B} \right) \] (8.25)

When collisions vanish, the conductivity becomes infinite and, in order to have only finite currents, we must have
\[ \mathbf{E} + \frac{1}{c} \mathbf{V} \times \mathbf{B} = 0 \] (8.26)
or
\[ \mathbf{E} = -\frac{1}{c} \mathbf{V} \times \mathbf{B} \] (8.27)

Under this infinite conductivity, low frequency condition, no charge imbalances are allowed and we have \( \rho_c = 0 \). Under these ideal MHD conditions, our basic equations (8.13), (8.14), (8.15), (8.20), (8.22), and (8.23) become

\[
\begin{align*}
\partial_t \rho_M + \nabla \cdot (\rho_M \mathbf{V}) &= 0 \\
\rho_M \partial_t \mathbf{V} &= -\nabla P + \frac{1}{c} \mathbf{J} \times \mathbf{B} \\
\nabla \times (\mathbf{V} \times \mathbf{B}) &= \partial_t \mathbf{B} \\
\nabla \times \mathbf{B} &= \frac{4\pi}{c} \mathbf{J}
\end{align*}
\] (8.28–8.31)

where the low frequency assumption is used to ignore \((1/c)(\partial \mathbf{E}/\partial t)\) on the right of (8.31).

We shall not attempt to further justify (8.28) to (8.31); instead, we shall take for granted that these equations can be justified in useful physical situations. In the next section, we shall use these equations to consider the equilibrium and stability of various plasma configurations.

### 8.2 MHD Equilibrium

In many cases one is interested in the equilibrium configurations of a plasma. Once the equilibrium is found, one then asks whether or not the equilibrium is stable. For example, the problem of the earth's magnetosphere and its interaction with the solar wind can be approached by first looking for MHD equilibria. (Since equilibrium implies that all zeroth order quantities have no time derivatives, we can feel some confidence in using the ideal MHD equations to look for equilibria.)

Once we find the zeroth order quantities \( \mathbf{B}^0, \mathbf{V}^0, \mathbf{J}^0 \), and \( \rho_M^0 \) (and thus \( P^0 \)) satisfying the ideal MHD equations (8.28–8.31) with \( \partial_t \to 0 \), we can then linearize about the equilibrium to determine whether it is stable. In other words, we let \( \rho_M = \rho_M^0 + \rho_M^1 \), etc., and \( \partial_t \to -i\omega \), and we solve for all possible values of \( \omega \). If one of these values of \( \omega \) has \( \text{Im}(\omega) > 0 \), we have instability and any tiny perturbation of the equilibrium will grow as \( \exp \{\text{Im}(\omega)t\} \) until the equilibrium is destroyed. If no unstable values of \( \omega \) are found, then we have MHD stability, but this does not imply overall stability. Much of the high frequency physics has been lost in first
going from the Vlasov equation to the two-fluid equations, and in next adding the
two-fluid equations to obtain the MHD equations. A system that is MHD stable
may well be unstable when two-fluid effects or Vlasov effects are considered. Thus,
MHD stability is a necessary but not a sufficient condition for overall stability.

Before proceeding to questions of MHD equilibrium and stability, let us try to
gain a measure of intuition regarding our MHD equations. From Ohm's law
(8.25) and Maxwell's equations (neglecting the displacement current)

$$\nabla \times \mathbf{B} = \frac{4\pi \sigma}{c} \mathbf{J} \quad (8.32)$$

and

$$\nabla \times \mathbf{E} = -\frac{1}{c} \partial_t \mathbf{B} \quad (8.33)$$

we obtain

$$\nabla \times (\nabla \times \mathbf{B}) = \frac{4\pi \sigma}{c} \left[ -\frac{1}{c} \partial_t \mathbf{B} + \frac{1}{c} \nabla \times (\nabla \times \mathbf{B}) \right] \quad (8.34)$$

or

$$\partial_t \mathbf{B} = \nabla \times (\nabla \times \mathbf{B}) + \frac{c^2}{4\pi \sigma} \nabla^2 \mathbf{B} \quad (8.35)$$

Thus, the magnetic field at a point in a plasma can be changed by the fluid
convection, the first term on the right side of (8.35), or by diffusion due to the
second term on the right side of (8.35). When \( \mathbf{V} = 0 \), (8.35) is

$$\partial_t \mathbf{B} = \frac{c^2}{4\pi \sigma} \nabla^2 \mathbf{B} \quad (8.36)$$

which is the standard form of a diffusion equation; the constant \( c^2/4\pi \sigma \) is known
as the magnetic diffusivity. Dimensional analysis of (8.36) shows that the field can
diffuse away with a diffusion time \( \tau_D \) given by

$$\tau_D \sim \frac{4\pi \sigma \mathcal{L}^2}{c^2} \quad (8.37)$$

where \( \mathcal{L} \) is the scale length. Since the conductivity \( \sigma \) is inversely proportional to the
collision rate, the physics of the diffusion must involve the disruption of particle
orbits due to collisions, which in turn disrupts the current that gives rise to the
magnetic fields; the disruption of the current allows the magnetic field to diffuse.

We consider next a very important concept, that of frozen-in field lines. Consider
a surface \( \Delta S \) drawn perpendicular to the field lines, and suppose that the
boundary of this surface is moving with some specified velocity field (Fig. 8.1).
What is the rate of change of the total magnetic flux

$$\Phi \equiv \int_{\Delta S} d\mathbf{A} \cdot \mathbf{B} \quad (8.38)$$

through the surface \( \Delta \Sigma \)? It is

$$\Phi = \int_{\Delta S} d\mathbf{A} \cdot \mathbf{B} + \int_{\Delta \Sigma} d\mathbf{A} \cdot \mathbf{B} \quad (8.39)$$
where the first term gives the contribution from the time rate of change of $\mathbf{B}$, and the second term gives the contribution from the movement of the boundary of the surface $\Delta S$. At every point on the boundary of $\Delta S$, the rate of change of the area enclosed by the boundary is proportional to the perpendicular component of $\mathbf{V}$ at that point, and therefore it is given by $\mathbf{V} \times d\mathbf{l}$. Thus, (8.39) is

$$
\dot{\Phi} = \int_{\Delta S} d\mathbf{A} \cdot \frac{\partial \mathbf{B}}{\partial t} + \oint \mathbf{B} \cdot (\mathbf{V} \times d\mathbf{l})
$$

(8.40)

In ideal MHD ($\sigma \to \infty$) we define the surface $\Delta S$ to be attached to the fluid, and we evaluate (8.40) for $\Phi$. We first integrate (8.30) over the surface $\Delta S$, obtaining

$$
\int_{\Delta S} d\mathbf{A} \cdot \partial_t \mathbf{B} = \int_{\Delta S} d\mathbf{A} \cdot [\nabla \times (\mathbf{V} \times \mathbf{B})]
$$

(8.41)

If we recall Stoke's theorem,

$$
\int_{\Delta S} (\nabla \times \mathbf{C}) \cdot d\mathbf{A} = \oint \mathbf{C} \cdot d\mathbf{l}
$$

(8.42)

(8.41) becomes

$$
\int_{\Delta S} d\mathbf{A} \cdot \partial_t \mathbf{B} = \oint d\mathbf{l} \cdot (\mathbf{V} \times \mathbf{B})
$$

(8.43)

Next recalling the vector identity

$$
\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C}) = (\mathbf{A} \times \mathbf{B}) \cdot \mathbf{C}
$$

(8.44)

we find

$$
\int_{\Delta S} d\mathbf{A} \cdot \partial_t \mathbf{B} + \oint \mathbf{B} \cdot (V \times d\mathbf{l}) = 0
$$

(8.45)

But by (8.40), the left side of (8.45) is just the total time rate of change of $\Phi$ through the surface $\Delta S$; therefore

$$
\dot{\Phi} = 0
$$

(8.46)

as long as the surface $\Delta S$ moves with the fluid.

Suppose that at $t = 0$ we draw two surfaces $\Delta S_1$ and $\Delta S_2$, and we then sweep the surfaces along the instantaneous field lines to form two flux tubes, as shown in Fig. 8.2. If the two surfaces $\Delta S_1$ and $\Delta S_2$ intersect at one point, then there is one
special field line that is the line at which the two flux tubes touch. By coloring the fluid in one flux tube red and the fluid in the other tube blue, we can follow the two flux tubes forever. For any reasonable flow, the tubes will always touch, and the line of touching identifies that particular magnetic field line forever. Thus, in ideal MHD, we can similarly label each and every field line, and we can say that the plasma is frozen to the field lines.

In nonideal MHD ($\sigma \neq \infty$), it becomes much more difficult to label field lines. This is true partially because lines can disappear because of resistivity.

Let us now return to consider the requirements for an MHD equilibrium. Looking for equilibrium solutions to (8.28)–(8.31), with no fluid flow, we require that

$$0 = - \nabla P + \frac{1}{c} J \times B$$  \hspace{1cm} (8.47)

and

$$\nabla \times B = \frac{4\pi}{c} J$$  \hspace{1cm} (8.48)

which yield

$$\nabla P - \frac{1}{4\pi} (\nabla \times B) \times B = 0$$  \hspace{1cm} (8.49)

Recalling

$$(\nabla \times B) \times B = (B \cdot \nabla)B - \frac{1}{2} \nabla B^2$$  \hspace{1cm} (8.50)

we have

$$\nabla P + \frac{1}{8\pi} \nabla B^2 = \frac{1}{4\pi} (B \cdot \nabla)B$$  \hspace{1cm} (8.51)

When $(B \cdot \nabla)B = 0$, this is

$$\nabla \left( P + \frac{B^2}{8\pi} \right) = 0$$  \hspace{1cm} (8.52)

which leads us to define the magnetic pressure $B^2/8\pi$, and to state that in equilibrium, magnetic pressure must balance plasma pressure (Fig. 8.3),

$$P + \frac{B^2}{8\pi} = \text{constant}$$  \hspace{1cm} (8.53)

Returning to (8.47), we see that in equilibrium,
\[ \nabla P = \frac{1}{c} \mathbf{J} \times \mathbf{B} \]  \hspace{1cm} (8.54)

so that \( \mathbf{B} \cdot \nabla P = \mathbf{J} \cdot \nabla P = 0 \); in other words, \( \mathbf{B} \) and \( \mathbf{J} \) lie along surfaces of constant pressure.

Let us consider two simple cases of plasma equilibria, the \textit{theta pinch} and the \textit{z-pinch}. In the theta pinch, capacitor plates are discharged about a cylindrical conductor, as shown in Fig. 8.4. The azimuthal \( \mathbf{J} \) makes a \( \mathbf{B} \) into the paper; the \( \mathbf{B} \) into the paper induces an azimuthal \( \mathbf{E} \) in the direction opposite to \( \mathbf{J} \), which in turn produces an internal current in the plasma in the direction opposite to \( \mathbf{J} \). A hypothetical final state could be as shown in Fig. 8.5 where the central plasma region has \( \mathbf{B} = 0 \). The pressures are then as shown in Fig. 8.6 so that \( P + B^2/8\pi = \text{constant} \), and there is an azimuthal current sheet at \( r_0 \) such that

\[ \nabla P = \frac{1}{c} \mathbf{J} \times \mathbf{B} \]  \hspace{1cm} (8.55)

is satisfied (Fig. 8.7).

A second possible equilibria is the \textit{z-pinch}, where a current flows along a plasma, and the plasma is confined by its own magnetic field and its own current
through the \( \mathbf{J} \times \mathbf{B} \) force, as shown in Fig. 8.8. Then in cyclindrical coordinates we have

\[
\nabla P = \frac{1}{c} \; \mathbf{J} \times \mathbf{B} = \frac{1}{4\pi} (\nabla \times \mathbf{B}) \times \mathbf{B}
\]

or

\[
\frac{\partial P}{\partial r} = -\frac{B_\theta}{4\pi r} \frac{\partial}{\partial r} (rB_\theta)
\]

The solution of (8.57) will be left for one of the problems; here we merely note that (8.57) does have well-balanced solutions for \( B_\theta(r) \) and \( P(r) \).

Before closing this discussion of equilibrium, we note two related points. First, because

\[
P + \frac{B^2}{8\pi} = \text{constant}
\]

the magnetic field is smaller inside a plasma \((P > 0)\) than outside a plasma \((P = 0)\). This is another illustration of the fact that a plasma is diamagnetic; we have seen this before in considering single particle motion.

Second, we notice from (8.48) and (8.49) that when \( \mathbf{J} \) is parallel to \( \mathbf{B} \), we have

\[
\nabla P = 0
\]

and

\[
(\nabla \times \mathbf{B}) \times \mathbf{B} = 0
\]
which is known as the *force free* situation. Any magnetic field for which
\[ \nabla \times \mathbf{B}(x) = f(x)\mathbf{B}(x) \quad (8.61) \]
satisfies (8.60).

In the next section we proceed to discuss the stability of our equilibria. It is the unfortunate case that both the theta pinch and z-pinch are unstable, as well as the simple mirror machine. We shall find that stable equilibria are possible, but only when certain criteria are satisfied.

### 8.3 MHD Stability

In the last section we found various examples of MHD equilibria. We must now ask whether those equilibria are stable. There are two ways of doing this. The first is to linearize the equations of motion about the zero-order equilibrium, and solve for the frequencies in exactly the same way in which we previously found linear waves. If one of these frequencies has \( \text{Im}(\omega) > 0 \), then \( \exp(-i\omega t) \sim \exp[\text{Im}(\omega)t] \) will grow with time, and the system is unstable. The second is to consider the total energy of a system, and to ask whether that energy increases or decreases under a perturbation. If the energy increases, the perturbation will not grow. If the energy decreases, the perturbation can happen and have energy left over to go into kinetic energy of expansion; this is the mark of instability.

The first method is to linearize the equations of motion. In ideal MHD, these are (8.28) to (8.31). For example, consider a plasma held up against the force of
gravity by a magnetic field, as in Fig. 8.9. For this example, because we generalize the force equation (8.29) to include gravity, we have

$$\rho_M \partial_t \mathbf{V} = - \nabla P + \frac{1}{c} \mathbf{J} \times \mathbf{B} + \rho_M \mathbf{g}$$

(8.62)

Since $|\mathbf{B}|$ has a discontinuity at $z = 0$, (8.31) predicts a sheet current at $z = 0$ in the $(-\hat{y})$-direction. The equilibrium quantities are, generalizing (8.51) and (8.52),

$$\frac{d}{dz} \left( P + \frac{B^2}{8\pi} \right) = - \rho_M \mathbf{g}$$

(8.63)

We next consider a perturbed fluid velocity at the plasma-vacuum interface with sinusoidal variation only along $y$, an undetermined variation in $z$, and no variation in $x$.

$$\mathbf{V} = \mathbf{v}(z) \exp(-i\omega t + iky)$$

(8.64)

where $\mathbf{v} = (0, v_y, v_z)$. It can then be shown [1] that instability results, with

$$\omega^2 = -kg$$

(8.65)

or

$$\omega = \pm i(kg)^{1/2}$$

(8.66)

which implies instability. This is called the Kruskal-Schwarzchild instability, and is the MHD analog of the fluid Rayleigh-Taylor instability.

It is interesting to consider the microscopic physics of this instability. Recall the current in the $-\hat{y}$-direction. Microscopically, this current is due to the $\mathbf{g} \times \mathbf{B}$ drifts of the particles on the plasma surface. Since this drift is proportional to mass (why?), the ions are drifting much faster. Now consider the initial perturbation, as shown in Fig. 8.10. Since the ions drift to the left, and the electrons drift to the right, charges build up as shown. This creates an electric field as shown. The plasma on the surface then performs an $\mathbf{E} \times \mathbf{B}$ drift, down in the left section and
up in the right section, thus intensifying the initial perturbation and leading to instability.

A similar analysis could be carried out for other equilibria, such as the theta pinch and z-pinch equilibria considered in the previous section. Consider the z-pinch equilibrium, and perturbations \( \sim \exp (-i\omega t + im\theta + ikz) \), where \( \theta \) is the azimuthal angle (Fig. 8.11). For \( m = 0 \), the instability is known as the sausage instability (Fig. 8.12). For \( m = 1 \), the instability is known as the kink instability. Higher values of \( m \) are known as flute instabilities, because their perturbations resemble fluted Greek columns.

We come to the second method of treating the question of stability in MHD systems, the energy principle. Consider a ball in a potential well, as shown in Fig. 8.13. In the unstable case, a small change in the particle's position leads to a decrease in the particle's potential energy; the difference in energy is available for kinetic energy and the implication is instability. On the other hand, the stable case is characterized by a positive change in potential energy for a small perturbation; thus, the perturbation is prohibited and the system is stable. It is interesting to contemplate the modification of these ideas when nonlinear effects are included.

It turns out that plasma systems behave in the same way. The energy of a plasma, which potentially could be turned into the kinetic energy of instability, is the integral over its volume of \( B^2 / 8\pi \), the magnetic energy, plus its internal kinetic energy \( \frac{1}{2} \dot{T} \) per particle (\( T_e = T_i = T \)). Thus, the plasma energy \( W \) is

\[
W = \int_V dV \frac{B^2}{8\pi} + \frac{3}{2} \int_V dV nT \tag{8.67}
\]

or

\[
W = \int_V dV \left( \frac{B^2}{8\pi} + \frac{3}{2} \frac{\dot{T}}{T} \right) \tag{8.68}
\]

If a hypothetical perturbation causes a decrease in \( W \), the system is unstable. (We will not prove this here.) If \( W \) increases, the system is stable to that perturbation.

![Fig. 8.12 Spatial variation of displacement for an \( m = 0 \) instability.](image_url)
Fig. 8.13 Examples of stability: (a) unstable; (b) stable; (c) linearly stable, nonlinearly unstable; (d) linearly unstable, nonlinearly stable.

(Note Murphy's eighth law: To prove instability, one needs to find only one unstable perturbation. To prove stability, one needs to prove stability for each and every possible perturbation.)

One could apply this technique to each of the equilibria considered previously; each would yield a change $\delta W < 0$ for the types of perturbations considered before. Here we consider the more general problem of the hypothetical interchange of two neighboring tubes of magnetic flux. If this leads to $\delta W < 0$, we will call it an interchange instability (Fig. 8.14). We consider separately the change of magnetic energy $W_m$,

$$W_m = \int dV \frac{B^2}{8\pi}$$  \hspace{1cm} (8.69)

and the change of internal plasma energy $W_p$,

$$W_p = \frac{3}{2} \int dV P$$  \hspace{1cm} (8.70)

The interchange is accomplished by moving tube 2 to where 1 used to be. Then

$$W_m = \sum_{i=1,2} \int_0^{l_i} dl_i A_i \frac{B_i^2}{8\pi}$$  \hspace{1cm} (8.71)

where $A_i$ is the cross-sectional area, and $l_i$ is the length of the $i$th flux tube. But in a flux tube the flux is constant; therefore $\phi_i = B_i A_i$, or

$$W_m = \sum_{i=1,2} \frac{\phi_i^2}{8\pi} \int_0^{l_i} \frac{dl_i}{A_i}$$  \hspace{1cm} (8.72)

The change $\delta W_m$ in $W_m$ by moving 1 to 2 is [1 keeps its flux but finds a new $l_i$ and $A_i$]

Fig. 8.14 Two neighboring flux tubes.
\[(\delta W_m)_{\Theta \rightarrow \Theta} = \frac{\varphi_1^2}{8\pi} \int_0^{l_1'} \frac{dl_1'}{A_2} - \frac{\varphi_2^2}{8\pi} \int_0^{l_1'} \frac{dl_1'}{A_1} \quad (8.73)\]

while the change for \(\Theta \rightarrow \Theta\) is
\[(\delta W_m)_{\Theta \rightarrow \Theta} = \frac{\varphi_2^2}{8\pi} \int_0^{l_1'} \frac{dl_1'}{A_1} - \frac{\varphi_2^2}{8\pi} \int_0^{l_1'} \frac{dl_1'}{A_2} \quad (8.74)\]

The total change, adding (8.73) to (8.74), is then
\[\delta W_m = \left[ \left( \frac{\varphi_2^2}{8\pi} - \frac{\varphi_1^2}{8\pi} \right) \left[ \int_0^{l_1'} \frac{dl_1'}{A_1} - \int_0^{l_1'} \frac{dl_1'}{A_2} \right] \right] \quad (8.75)\]

or
\[\delta W_m = \frac{\delta[\varphi^2]}{8\pi} \int \frac{dl}{A} \quad (8.76)\]

If we pick two flux tubes with equal flux, we have
\[\delta W_m = 0 \quad (8.77)\]

With two flux tubes of equal flux, we next calculate the change in internal energy of the flux tubes, as the plasma expands or contracts to fit into a changing volume (Fig. 8.15).

The change in internal energy as we move the plasma in \(V_1\) to the volume \(V_2\) is (assuming \(|V_2 - V_1|/V_1 < \ll 1\))
\[\delta W_p_{\Theta \rightarrow \Theta} = \frac{3}{2} \delta(PV) = \frac{3}{2} \delta \left( \frac{PV\gamma}{V^{\gamma-1}} \right) \]
\[= \frac{3}{2} (PV\gamma) (1 - \gamma) \delta V \]
\[= \frac{3}{2} (PV\gamma) (1 - \gamma) V_1^{\gamma-1} \delta V \]
\[= \frac{3}{2} (PV\gamma) (1 - \gamma) (V_2 - V_1) \quad (8.78)\]

Fig. 8.15  Neighboring flux tubes with equal flux may have different areas and volumes.
where we have approximated \( V \approx V_1 \approx V_2 \) in the denominator only, and we have used the fact that \( PV^\gamma = \) constant in an adiabatic compression; assuming a three-dimensional compression we have \( \gamma = 5/3 \).

Next, the change \( \delta W_p \) is obtained from (8.78) by interchanging \( \bigcirc \) and \( \bigcirc \); adding the two pieces yields

\[
\delta W_p = -\frac{3}{2} \left(1 - \gamma \right) \left[ \frac{(PV^\gamma)_2}{V_2^{\gamma}} - \frac{(PV^\gamma)_1}{V_1^{\gamma}} \right] (V_2 - V_1)
\]  
(8.79)

Approximating \( V_1 \approx V_2 \) in the denominator only, we have

\[
\delta W_p = -\frac{3}{2} \left(1 - \gamma \right) \frac{(PV^\gamma)}{V_1^{\gamma}} \delta(PV^\gamma) \delta V
\]  
(8.80)

where \( \delta(PV^\gamma) \) now means \( (PV^\gamma)_2 - (PV^\gamma)_1 \). With \( \gamma = 5/3 \) this is

\[
\delta W_p = V_1^{-\gamma} \delta(PV^\gamma) \delta V
\]  
(8.81)

or

\[
\delta W_p = V_1^{-\gamma} \delta V (\delta PV_1^{\gamma} + \gamma P_1 V_1^{\gamma-1} \delta V)
\]  
(8.82)

Now suppose we are in a low density part of the plasma, so that \( P(\delta V/V) \ll \delta P \). (This is possible because \( \delta V \) will be very small when magnetic fields are large; recall that the flux of the two tubes is equal and we only need a small magnetic field gradient \( \nabla B^2/8\pi \sim B \nabla B \) to balance the particle pressure gradient \( \nabla P \)). Then

\[
\delta W_p = \delta V \delta P
\]  
(8.83)

If the plasma density decreases from 1 to 2, \( \delta P < 0 \), there will be instability \( \delta W_p < 0 \) if \( \delta V > 0 \) or

\[
\delta V = \delta \int dA = \varphi \delta \int \frac{dl}{B} > 0
\]  
(8.84)

so that the condition for instability is

Fig. 8.16 Magnetic field lines and plasma density in a cusp configuration.
Consider the simple mirror configuration of Fig. 8.14. As we go from (1) to (2), the length of $\int dl$ increases while $|B|$ decreases; (8.85) is easily satisfied and we find instability. The same result is easily obtained for both the $\theta$-pinch and the $z$-pinch.

Equation (8.85) leads to a very important principle, which we shall not prove rigorously here. This principle states: Whenever the field lines curve toward the plasma, the plasma is unstable. Likewise, when field lines curve away from the plasma, the plasma is interchange stable. Thus, the simple mirror and pinches are unstable, while the cusp is stable, as shown in Fig. 8.16. Since the field lines curve away from the plasma the cusp is interchange stable. Furthermore, the magnetic field is a minimum in the center of the plasma, so that minimum-$B$ is associated with interchange stability. The instability of the simple mirror has led mirror designers to look for a minimum-$B$ configuration. They accomplish this by putting coils, known as Joffe bars, along the axis of the mirror. The net result is a field configuration that everywhere curves away from the plasma, has a minimum of $|B|$ in the center, and is MHD stable (Fig. 8.17).

### 8.4 MICROSCOPIC PICTURE OF MHD EQUILIBRIUM

Magnetohydrodynamics is based on a picture of the plasma as a single fluid. Yet we know that the plasma consists of two species of charged particles. Thus, any topic in MHD can also be understood by considering the detailed orbits of the charged particles. In this section, we look at the topic of MHD equilibrium from a microscopic point of view.
Consider a plasma whose density varies smoothly in the \( x \)-direction, with magnetic field \( B_0 = B_0(x) \hat{z} \) (Fig. 8.18). Then the MHD equations (8.47) and (8.48) predict, in the steady state and in component form,

\[
\frac{\partial P}{\partial x} = \frac{1}{c} J_y B_0
\]  
(8.86)

and

\[
-\partial_x B_0 = \frac{4\pi}{c} J_y
\]  
(8.87)

Suppose that the ions are cold, \( T_i = 0 \), and the electron temperature \( T_e \) is a constant in space. Then at \( x = 0 \), (8.86) yields

\[
J_y = \frac{c}{B_0} T_e \frac{\partial n_0}{\partial x} < 0
\]  
(8.88)

so that our macroscopic picture is one where the plasma pressure is being balanced by the \( \mathbf{J} \times \mathbf{B} \) force. Suppose the ions are cold and very massive; then it is reasonable to suppose that the current is being contributed by the electrons, even though the one-fluid equations tell us nothing of the behavior of the individual species. If this is so, then there must be a mean electron flow speed in the \( \hat{y} \)-direction such that

\[
J_y = -e n_0 \langle v_y \rangle_{\text{electrons}}
\]  
(8.89)

or from (8.88)

\[
\langle v_y \rangle_{\text{electrons}} = -\frac{c T_e}{e B_0} \frac{1}{n_0} \frac{\partial n_0}{\partial x}
\]  
(8.90)

which with \( L_n^{-1} \equiv (1/n_0)(dn_0/dx) > 0 \) is

\[
v_{de} = \frac{v_e^2}{|\Omega_e| L_n}
\]  
(8.91)

where \( v_{de} \) is the electron diamagnetic drift speed, and \( v_e \) is, as usual, the electron thermal speed.

**Fig. 8.18** Coordinate system for MHD equilibrium.
EXERCISE  Where does the "diamagnetic" come from?

Now let us look at the single particle picture. The electrons are gyrating about the magnetic field in the x-y plane. There is no electric field, hence no $\mathbf{E} \times \mathbf{B}_0$ drift. There is no curvature of the field lines, hence no curvature drift. There will be a $\nabla B$ drift but, if we assume a very strong magnetic field, then only a tiny $\nabla B$ is needed to make $\nabla (P + B^2/8\pi) = 0$, and we can ignore the $\nabla B$ drift. So where does the single particle drift come from to make $v_{de}$ in (8.91)? The fact is that in terms of guiding centers, there is no drift, but in terms of fluid elements, there is a drift. Consider the x-y plane, as indicated in Fig. 8.19. Because there are more particles for $x < 0$ than for $x > 0$, a small area of the x-z plane will see more particles going through to the right than to the left; thus, there is a net flow of electrons to the right in every fluid element, and a net current to the left. This is true even though the guiding centers never move!

This concludes our introduction to magnetohydrodynamics. MHD is an extremely important approximation in plasma physics that is widely used in fusion plasma physics, solar physics, plasma astrophysics, and energy technology. For further discussion of MHD see Refs. [2]–[30].

**PROBLEMS**

8.1 Alfvén Waves

Linearize the ideal MHD equations (8.28) to (8.31) with $\rho_M = \rho_M^0$, $B = B_0 \hat{z} + B_1 \hat{y}$, $V = V_1 \hat{y}$, $J = J_y \hat{x}$, and $k = k \hat{y}$ to obtain the dispersion relation for Alfvén waves. Compare your result to the result (7.214) from the two-fluid theory, and explain any differences.

8.2 Magnetosonic Waves

For a cold plasma, linearize the ideal MHD equations (8.28) to (8.31) with $\rho_M = \rho_M^0$, $B = B_0 \hat{z} + B_1 \hat{z}$, $V = V_1 \hat{y}$, $J = J_y \hat{x}$, and $k = k \hat{y}$ to obtain the dispersion relation for fast magnetosonic waves. Compare your result to the result (7.227) from two-fluid theory, and explain any differences.
CHAPTER 9
Discrete Particle Effects

9.1 INTRODUCTION
There are many effects in a plasma that are associated with the discrete nature of the plasma particles. One of these effects is that of collisions, which is studied in Chapters 1 and 3 to 5. A collision is the interaction of one discrete particle with another discrete particle. There are also discrete particle effects that are due to the interaction of one discrete particle with the plasma as a whole. For example, a fast electron moving through a plasma emits Langmuir waves. This phenomena depends on the fact that the fast electron is indeed a discrete particle, but it does not require that the rest of the plasma be made up of discrete particles; thus, the rest of the plasma can be treated through the Vlasov approximation. This leads to an extremely useful approach known as the test-particle method.

Since the effects to be studied in this chapter are discrete particle effects, it might have made more sense to study them together with the discrete particle collisional effects. However, it turns out that the test-particle method relies heavily on the Vlasov dielectric function. Chapter 6 on Vlasov theory taught us many of the properties of this dielectric function, so that we can now comprehend the results of the test-particle method more easily.

9.2 DEBYE SHIELDING
As a first application of the test-particle method, let us calculate the Debye shielding of a test charge $q_f$ that moves through a uniform plasma with a constant speed $v_0$, starting from position $x_0 = 0$ at $t = 0$. For simplicity, we freeze the ions, and treat the plasma electrons via the Vlasov equation. The only discreteness in the problem is the test charge. Then Poisson’s equation is
\[ \nabla^2 \varphi(x, t) = -4\pi \rho \]
\[ = -4\pi e [n_0 - \int dv f_e(x, v, t)] - 4\pi q_T \delta(x - v_0 t) \]
\[ = 4\pi e \int dv f_i(x, v, t) - 4\pi q_T \delta(x - v_0 t) \]  
(9.1)

where \( f_e = f_0 + f_i \) and the \( f_0 \) term cancels the ion term. Assuming that the test charge makes only a small perturbation in the electron density, we can linearize the Vlasov equation to obtain
\[ \partial_t f_i(x, v, t) + v \cdot \nabla f_i = -\frac{e}{m_e} \nabla \varphi \cdot \nabla f_0(v) \]  
(9.2)

With these two equations, we use Laplace transform techniques to study the initial value problem. The test charge suddenly appears at \( x = 0 \) at \( t = 0 \), and the distribution function is initially unperturbed,
\[ f_i(x, v, t = 0) = 0 \]  
(9.3)

We Fourier transform (9.1) and (9.2) in space, and Laplace transform in time. The Fourier and Laplace transform conventions are stated in Chapter 5. The spatial Fourier transform of Poisson’s equation (9.1) is
\[ -k^2 \varphi(k, \omega) = 4\pi e \int dv f_i(k, v, \omega) - \frac{q_T}{2\pi^2} e^{-ik \cdot v_0 t} \]  
(9.4)

which has the Laplace transform
\[ -k^2 \varphi(k, \omega) = 4\pi e \int dv f_i(k, v, \omega) + \frac{(2\pi^2)^{-1} q_T}{i\omega - ik \cdot v_0} \]  
(9.5)

Because the initial value of \( f_i \) is zero, the Fourier–Laplace transform of the linearized Vlasov equation (9.2) is
\[ (-i\omega + ik \cdot v) f_i(k, \omega, v) = -\frac{e}{m_e} ik \cdot \nabla f_0(v) \varphi(k, \omega) \]  
(9.6)

Solving (9.6) for \( f_i \) and inserting in (9.5) yield
\[ k^2 \varphi(k, \omega) = -\frac{4\pi e^2}{m_e} \int dv \frac{k \cdot \nabla f_0(v)}{\omega - k \cdot v} \varphi(k, \omega) + \frac{i(2\pi^2)^{-1} q_T}{\omega - k \cdot v_0} \]  
(9.7)

The integrations of the two velocity directions perpendicular to \( k \) can be performed, yielding the form
\[ k^2 \varphi(k, \omega) \left[ 1 - \frac{\omega^2}{k^2} \int du \frac{d_u g(u)}{u - \omega/k} \right] = \frac{i(2\pi^2)^{-1} q_T}{\omega - k \cdot v_0} \]  
(9.8)

where in square brackets we recognize our old friend the Vlasov dielectric function (6.34). Thus,
\[ \varphi(k, \omega) = \frac{i(2\pi^2)^{-1} q_T}{k^2 \epsilon(k, \omega)(\omega - k \cdot v_0)} \]  
(9.9)

Next, the Laplace transform is inverted to obtain
\[ \varphi(k, t) = \int_L \frac{d\omega}{2\pi} e^{-i\omega t} \varphi(k, \omega) \]

\[ = \int_L \frac{d\omega}{2\pi} e^{-i\omega t} \frac{i(2\pi^2)^{-1} q_T}{k^2 \epsilon(k, \omega)(\omega - k \cdot v_0)} \]  

(9.10)

The pole structure of the integrand is as shown in Fig. 9.1, where for Maxwellian electrons \( \epsilon(k, \omega) \) has among others, the two zeros corresponding to Landau damped Langmuir waves. For this calculation, we can move the contour downward for \( t > 0 \) as in the calculation of Langmuir waves in Section 6.4. We ignore all of the transient contributions discussed in Section 6.4 (see Fig. 6.6). Furthermore, let us ignore the contribution from the Langmuir poles, which will damp away at large times. Then we pick up only the pole at \( \omega = k \cdot v_0 \), obtaining

\[ \varphi(k, t) = \frac{(2\pi^2)^{-1} q_T e^{-ik \cdot v_0 t}}{k^2 \epsilon(k, \omega) = k \cdot v_0} \]  

(9.11)

Since \( \epsilon \) is evaluated at the real frequency \( \omega = k \cdot v_0 \), we can use the exact formula (6.45),

\[ \epsilon(k, \omega) = 1 - \frac{\omega_e^2}{k^2} P \int du \frac{d_u g(u)}{u - (\omega/k)} - \pi i \frac{\omega_e^2}{k^2} d_u g(u) \bigg|_{u = \omega/k} \]  

(9.12)

Let us work out several examples.

**EXAMPLE A VACUUM**

Letting the plasma disappear, \( \omega_e \to 0 \), we have \( \epsilon = 1 \). Then

\[ \varphi(k, t) = \frac{q_T}{2\pi^2 k^2} e^{-ik \cdot v_0 t} \]  

(9.13)

Performing the inverse Fourier transform we have

\[ \varphi(x, t) = \int dke^{ik \cdot x} \varphi(k, t) \]

\[ = \int dke^{ik \cdot x - ik \cdot v_0 t} \frac{q_T}{2\pi^2 k^2} \]  

(9.14)
This integral can be performed in spherical coordinates, letting the \( k_r \)-axis be in the direction of \( \mathbf{x} - \mathbf{v}_0t \). Then
\[
k \cdot (\mathbf{x} - \mathbf{v}_0t) = k|\mathbf{x} - \mathbf{v}_0t|\cos \theta
\] (9.15)
and
\[
\varphi(x, t) = \frac{q_T}{2\pi^2} \int_0^\infty dk \int_0^\pi d\theta \sin \theta e^{ik|x - \mathbf{v}_0t|\cos \theta} \] (9.16)
With \( u = \cos \theta, du = -\sin \theta d\theta \), we have
\[
\varphi(x, t) = \frac{q_T}{\pi} \int_0^\infty dk \int_{-1}^1 du e^{ik|x - \mathbf{v}_0t|u}
\]
\[
= \frac{2q_T}{\pi} \frac{1}{|x - \mathbf{v}_0t|} \left[ \int_0^\infty \frac{\sin(k|x - \mathbf{v}_0t|)}{k} dk \right]
\]
\[
\int_0^{\infty} \frac{dz}{z} \sin z
\]
\[
\pi/2
\]
or
\[
\varphi(x, t) = \frac{q_T}{|x - \mathbf{v}_0t|}
\] (9.18)
Thus, we regain the potential due to a point charge in vacuum, moving with velocity \( \mathbf{v}_0 \).

**EXAMPLE B  TEST CHARGE AT REST IN PLASMA (\( \mathbf{v}_0 \ll \mathbf{v}_e \))**

For a test charge at rest, or moving very slowly (\( |\mathbf{v}_0| \ll \mathbf{v}_e \)), we expect to regain the Debye shielding of Chapter 1 (for motionless ions). Setting \( \omega = k \cdot \mathbf{v}_0 \approx 0 \), we have, taking the electrons Maxwellian [see Eq. (6.24)],
\[
e(k, \omega = 0) = 1 - \frac{\omega^2}{k^2} \int du \frac{d_u g(u)}{u}
\]
\[
- \int du \frac{g(u)}{v_e^2}
\]
\[
1/v_e^2
\]
or
\[
e(k, \omega = 0) = 1 + \frac{\omega^2}{k^2 v_e^2} = 1 + \frac{1}{k^2 \lambda_e^2}
\] (9.19)
which is the “static dielectric function” with fixed ions. The potential is then
\[
\varphi(k, t) = \frac{(2\pi^2)^{\frac{1}{2}} q_T}{k^2 e(k, \omega = 0)} = \frac{(2\pi^2)^{\frac{1}{2}} q_T}{k^2 + k_e^2}
\] (9.21)
where we have defined the Debye wave number
\[ k_e \equiv \lambda_e^{-1} \] (9.22)
without any factor of \(2\pi\). Then
\[
\varphi(x,t) = \int dk \, e^{ik \cdot x} \varphi(k,t)
\]
\[
= \frac{q_T}{2\pi^2} \int_0^\infty 2\pi k^2 \, dk \int_0^\pi d\theta \sin \theta \frac{e^{ikx \cos \theta}}{k^2 + k_e^2}
\]
\[
= \frac{q_T}{\pi} \int_0^\infty dk \frac{k^2}{k^2 + k_e^2} \int_{-1}^1 du \, e^{ikxu}
\]
\[
= \frac{2}{\pi x} q_T \int_0^\infty dk \frac{k \sin kx}{k^2 + k_e^2} \] (9.23)
where the substitution \(u' = \cos \theta\) has been used. Because the integrand is even in \(k\), we can extend the integration to \(-\infty\) and use contour techniques. We find \((x \equiv |x| > 0)\)
\[
\frac{1}{2} \int_\infty^{-\infty} dk \frac{k \sin kx}{k^2 + k_e^2} = \frac{1}{2} \int_\infty^{-\infty} dk \frac{k}{(k + ik_e)(k - ik_e)} \left( \frac{e^{ikx} - e^{-ikx}}{2i} \right)
\]
\[
= \frac{2\pi i}{2(2i)} \left[ \frac{ik_e}{2ik_e} e^{i(kx)x} + \frac{-ik_e}{-2ik_e} e^{-i(kx)x} \right]
\]
\[
= \frac{\pi}{2} e^{-x/\lambda_e}.
\] (9.24)
so that
\[
\varphi(x,t) = \frac{q_T}{x} e^{-x/\lambda_e} \quad v_0 \ll v_e \] (9.25)
which is exactly what we expect for a Debye shielded test particle. Note that this formula is valid not only for motionless particles, but also for moving particles as long as \(v_0 \ll v_e\). (See Refs. [1]–[9].)

**EXAMPLE C  VERY FAST TEST CHARGE \((v_0 \gg v_e)\)**

For a very fast test charge, the dielectric function is
\[
e(k,\omega = k \cdot v_0) \approx 1 - \frac{\omega_e^2}{k^2} P \int_{-\infty}^{\infty} du \, \frac{d_u g(u)}{u - k \cdot v_0 / k}
\]
\[
\approx 1 + \frac{\omega_e^2}{k k \cdot v_0} \int_{-\infty}^{\infty} du \, \underbrace{d_u g}_{0}
\]
\[
\approx 1
\] (9.26)
where we have ignored \(u\) compared to \(k \cdot v_0 / k\) in the denominator. But this is the same result as for a test charge in vacuum (Example A), so we find
Fig. 9.2 Steady-state equipotential contours, as measured in the frame of a moving test charge at the origin, with charge \( q_T \) and speed \( v_0/2^{\frac{1}{2}} v_e = 0.1 \). Contour labels indicate the value of \( \varphi \lambda_e/q_T \). Unclosed, unlabeled contour is at zero potential. From Ref. [9].

Fig. 9.3 Same as Fig. 9.2, for \( v_0/2^{\frac{1}{2}} v_e = 0.3 \).
Fig. 9.4 Same as Fig. 9.2, for \( \frac{v_0}{2} \frac{1}{c} = 1.0 \).

Fig. 9.5 Same as Fig. 9.2, for \( \frac{v_0}{2} \frac{1}{c} = 2.0 \).
Fig. 9.6  Same as Fig. 9.2, for $v_0/\sqrt{2}v_c = 3.0$.

Fig. 9.7  Same as Fig. 9.2, for $v_0/\sqrt{2}v_c = 10.0$. 

218
The plasma does not have time to "see" a fast test charge, and thus does not have time to respond and shield. (See Refs. [1]–[9].)

We have seen that a fast particle has no shielding, while a slow particle is completely shielded. A particle moving at intermediate speeds will be partially shielded. The words fast, slow, and intermediate will depend on which plasma species we are talking about. Figures 9.2 to 9.7 show the transition from the Debye shielding of an almost motionless particle \(v_0/(2^{1/2} v_e) = 0.1\) in Fig. 9.2 to the almost unsheilded behavior of a fast particle \(v_0/(2^{1/2} v_e) = 10.0\) in Fig. 9.7.

In the next section, we continue to exploit the test particle approach, calculating the equilibrium level of fluctuations in a plasma.

### 9.3 FLUCTUATIONS IN EQUILIBRIUM

In the previous section, we computed the electrostatic potential in a plasma due to a single test charge. We found that the rest of the plasma could be treated by the Vlasov equation.

In this section, we want to use the same ideas to compute the average level of electric field fluctuations in an equilibrium plasma. We do this by considering each and every plasma particle as a test charge. Each test charge sees the rest of the plasma as a Vlasov plasma, and it emits waves satisfying the Cerenkov condition \(\omega = k \cdot v_0\), where \(v_0\) is the velocity of the test charge. Likewise, waves are damped via Landau damping, which again involves the resonance condition \(\omega = k \cdot v_0 = ku\) where \(v_0\) is now the velocity of the particle that is doing the Landau damping, and \(u \equiv k \cdot v_0/k\). Thus, we have a steady-state situation, with waves being emitted and absorbed. At each point in the plasma, the electric field is fluctuating wildly in space and time. However, the ensemble averaged electric field energy density is a constant in space and in time. It is this ensemble averaged electric field energy density that we wish to calculate.

The process considered here is an example of the *principle of detailed balance*, which states that to every emission process, there is a corresponding damping process, and vice versa. Cerenkov emission of Langmuir waves corresponds to Landau damping of Langmuir waves. In steady state, these two processes are balanced; the average rate of wave emission equals the average rate of wave damping.

Note that here we are using the term "wave" in its most general sense; we have fluctuations of all frequencies and all wave numbers, including the normal modes that we call "Langmuir waves."

The mathematics involved in this calculation is straightforward. Recall from Eq. (9.11) that the potential due to a single test charge is written in wave number space as

\[
\phi(k,t) = \frac{(2\pi)^{-1} q \ e^{-ik \cdot x_0(t)}}{k^2 \epsilon(k,\omega = k \cdot v_0)}
\]  

(9.28)
where in the exponent we have specified the orbit \( v_0 t \) by the expression \( x_0(t) \). Since

\[
E(x,t) = - \nabla \varphi(x,t)
\]  
(9.29)

we have

\[
E(k,t) = - i \hbar \varphi(k) \mp - (2\pi^2)^{-1} i q_T \frac{k e^{-i k \cdot x_0(t)}}{k^2 \epsilon(k, \omega = k \cdot v_0)}
\]  
(9.30)

so that

\[
E(x,t) = \int dk \, e^{i k \cdot x} E(k,t)
\]

\[
= - (2\pi^2)^{-1} q_T i \int dk \, \frac{k e^{i k \cdot x - i k \cdot x_0(t)}}{k^2 \epsilon(k, \omega = k \cdot v_0)}
\]  
(9.31)

Equation (9.31) gives the electric field at point \( x \) due to a particle with orbit \( x_0(t) \). If we add up the fields at \( x \) from all particles in the plasma, and take the ensemble average, we have

\[
\langle E(x,t) \rangle = \int dv_0 \int dx_0 \, E(x,t) f_0(x_0, v_0)
\]  
(9.32)

where \( f_0 \) is the zero order distribution function. The function \( f_0 \) is the probability density for plasma particles to have velocity \( v_0 \) and position \( x_0 \); thus, the ensemble average of any plasma property that is caused by the discrete plasma particles is given by an equation like (9.32).

In a uniform isotropic plasma, there is no preferred direction; therefore we expect (9.32) to vanish. This indeed happens.

**EXERCISE** By performing the \( x_0 \) integration, convince yourself that (9.32) vanishes.

Next, consider the ensemble average electric field energy density in the plasma,

\[
W \equiv \frac{1}{8\pi} \langle E(x) \cdot E(x) \rangle
\]  
(9.33)

Since this is a positive definite quantity, we expect a nonzero result. Taking the ensemble average in the same way as in (9.32), we have

\[
W = \frac{1}{8\pi} \int dv_0 \int dx_0 \left( \frac{q_T}{2\pi^3} \right)^2 f_0(v_0)
\]

\[
\times \left[ \int dk \, \frac{k e^{i k \cdot x - i k \cdot x_0(t)}}{k^2 \epsilon(k, \omega = k \cdot v_0)} \right] \cdot \left[ \int dk' \, e^{-i k' \cdot x + i k' \cdot x_0(t)} \frac{k' e^{-i k' \cdot x + i k' \cdot x_0(t)}}{(k')^2 \epsilon(k', \omega = k' \cdot v_0)} \right]
\]  
(9.34)

where we have used \( E^*(x) = E(x) \) for the real electric field in the second set of square brackets. The \( x_0 \) integration yields \( (2\pi)^3 \delta(k - k') \) which facilitates the \( k' \) integration; we find
\[ W = \frac{q^2}{4\pi^2} \int d\nu f_0(\nu_0) \int d\mathbf{k} \frac{1}{k^2|\epsilon(\mathbf{k},\omega = \mathbf{k} \cdot \nu_0)|^2} \]  

(9.35)

We can perform the two velocity integrations in the directions perpendicular to \( \mathbf{k} \), and extract a factor of \( n_0 \), to obtain in the usual fashion

\[ W = \frac{e^2}{4\pi^2} n_0 \int du g(u) \int d\mathbf{k} \frac{1}{k^2|\epsilon(\mathbf{k},\omega = ku)|^2} \]  

(9.36)

Defining \( \omega \equiv ku \), we find

\[ W = \frac{n_0e^2}{2\pi} \int \frac{d\omega}{2\pi} \int d\mathbf{k} \frac{g(\omega/k)}{k^3|\epsilon(\mathbf{k},\omega)|^2} \]  

(9.37)

Thus, we can define an energy density \( W(\mathbf{k},\omega) \) such that

\[ W \equiv \frac{\langle E^2 \rangle}{8\pi} = \int \frac{d\omega}{2\pi} \int d\mathbf{k} W(\mathbf{k},\omega) \]  

(9.38)

with

\[ W(\mathbf{k},\omega) = \frac{n_0e^2 g(\omega/k)}{2\pi k^3|\epsilon(\mathbf{k},\omega)|^2} \]  

(9.39)

Since \( \omega \) is purely real, we have for the Vlasov–Poisson system the exact expression (9.12). Thus,

\[ |\epsilon(\mathbf{k},\omega)|^2 = \left[ 1 - \frac{\omega_c^2}{k^2} P \int du \left. \frac{d_u g(u)}{u - (\omega/k)} \right] \right]^2 \]  

\[ + \left[ \frac{\omega_c^2}{k^2} \pi d_\omega g(u)\right|_{\omega=\omega/k} \]  

(9.40)

We can easily perform the frequency integration in Eq. (9.38) in two simple limiting cases.

**CASE A: \( k \lambda_e << 1 \)**

This criterion is exactly the one for the existence of Langmuir waves. In this wave number regime we expect all of the energy in fluctuations to be concentrated in Langmuir waves with frequencies \( \omega \approx \pm \omega_c \). Then in the denominator of the real part of \( \epsilon \), we have \( \omega/k \approx \omega_c/k \) but \( \omega/k << \lambda_e^{-1} \); therefore \( \omega/k \approx \omega_c/k >> \omega_c \lambda_e = \nu_e \), which means that \( \omega/k >> u \) for almost all the range of \( u \) integration. Thus, we integrate by parts to obtain

\[ P \int du \left. \frac{d_u g(u)}{u - (\omega/k)} \right] = P \int du \frac{g(u)}{(u - (\omega/k))^2} \approx \frac{k^2}{\omega^2} \int du g(u) = \frac{k^2}{\omega^2} \]  

(9.41)

Thus

\[ |\epsilon(\mathbf{k},\omega)|^2 = \left( 1 - \frac{\omega_c^2}{\omega^2} \right)^2 + \left[ \frac{\omega_c^2}{k^2} \pi d_\omega g\right|_{\omega=\omega/k} \]  

(9.42)
Since this expression goes into the denominator of (9.38), we see that there will be a large contribution when $\omega \approx \pm \omega_e$. Thus, we evaluate the numerator $g(\omega/k) \sim g(\omega_e/k)$ and the term $d_\omega g |_{\omega/k} \approx d_\omega g |_{\omega_e/k}$ in the denominator at $\omega \approx \omega_e$. We are left with the integration in the form

$$I \equiv \int_{\omega_e - \Delta}^{\omega_e + \Delta} \frac{d\omega}{2\pi} \frac{1}{[1 - (\omega_e^2/\omega^2)]^2 + c^2} \approx \omega_e^4 \int_{\omega_e - \Delta}^{\omega_e + \Delta} \frac{d\omega}{2\pi} \frac{1}{(\omega^2 - \omega_e^2)^2 + c^2 \omega_e^2}$$

(9.43)

where $c^2$ is small; since the main part of the integral comes from $\omega \approx \omega_e$, we can let the limits of integration $\rightarrow \pm \infty$. With $y = \omega^2$, $dy = 2\omega d\omega$ we have

$$I = \frac{1}{4\pi} \int_{-\infty}^{\infty} dy \frac{\omega_e^5}{(y - \omega_e)^2 + c^2 \omega_e^4}$$

$$= \frac{\omega_e^3}{4\pi} \int_{-\infty}^{\infty} dy \frac{1}{[(y - \omega_e^2) + ic \omega_e^2][(y - \omega_e^2) - ic \omega_e^2]}$$

(9.44)

which can be done by contour integration; closing either up or down we find (multiplying by a factor of 2 to take into account the frequency regime near $\omega \approx -\omega_e$)

$$2I = \frac{2(2\pi i)\omega_e^3}{4\pi} \frac{1}{2ic \omega_e^2} = \frac{\omega_e}{2c}$$

(9.45)

so that

$$W = \int dk \frac{n_0 e^2}{2\pi k^3} g(\omega_e/k) \frac{\omega_e}{2} \left[ \frac{\omega_e^2}{k^2} \pi d_\omega g |_{\omega_e/k} \right]$$

(9.46)

For a Maxwellian, $g/d_\omega g |_{\omega_e/k} = v_e^2 k/\omega_e$; therefore we obtain

$$W = \int_{k < < k_e} \frac{dk}{(2\pi)^3/2} \left[ \frac{m v_e^3}{2} \right] \frac{\omega_e}{2} = \int_{k < < k_e} \frac{dk}{(2\pi)^3/2} \frac{T_e}{2}$$

(9.47)

so that in the regime $k \lambda_e << 1$, we find $T_e/2$ energy per unit $k$-space per unit real space.

Let us crudely evaluate the total amount of energy, per unit real space, in long wavelength ($k \lambda_e << 1$) fluctuations. To do this, we perform the integration in (9.47) over a spherical volume from $k = 0$ to $k = k_e \equiv \lambda_e^{-1}$. We obtain

$$W = \left( \frac{4}{3} \frac{\pi k_e^3}{(2\pi)^3} \right) \frac{1}{2} \frac{T_e}{2}$$

(9.48)

Multiplying numerator and denominator by $n_0$, and dropping all numerical factors, we crudely obtain

$$W \approx \frac{n_0 T_e}{n_0 \lambda_e^3}$$

(9.49)
or
\[
W \approx \frac{n_0 T_e}{\Lambda} \tag{9.50}
\]

Thus, the average long wavelength fluctuation energy density is very small; it is the average electron kinetic energy density divided by the number of particles in a Debye cube.

**CASE B:** \( k \lambda_e \gg 1 \)

When \( k \) is very large, we have from (9.12) that
\[
\epsilon(k, \omega) = 1 - \frac{\omega_e^2}{k^2} \int du \frac{d_u g(u)}{u - (\omega/k)}
\approx 1 - \frac{\omega_e^2}{k^2} \int du \frac{d_u g(u)}{u}
\approx 1 \tag{9.51}
\]

Then from (9.38),
\[
W = \int \frac{dk}{2 \pi} \frac{d \omega}{2 \pi n_0 e^2} \frac{n_0 e^2}{2 \pi k^3} g(\omega/k)
= \pi(4 \pi n_0 e^2) \int \frac{dk}{(2 \pi)^3} \frac{1}{2 \pi k^2} \int \left[ \frac{d u}{u} \right] g\left( \frac{\omega}{k} \right)
= \frac{m_e \omega_e^2}{2} \int \frac{dk}{(2 \pi)^3} \frac{1}{k^2}
= \frac{T_e}{2} \int \frac{dk}{(2 \pi)^3} \frac{1}{k^2 \lambda_e^2} \tag{9.52}
\]

Writing this in the form
\[
W = \int \frac{dk}{(2 \pi)^3} W(k) \tag{9.53}
\]
we have
\[
W(k) = \frac{T_e}{2} \frac{1}{k^2 \lambda_e^2}, \quad k \lambda_e \gg 1 \tag{9.54}
\]

which can be compared with (9.47) where
\[
W(k) = \frac{T_e}{2}, \quad k \lambda_e << 1 \tag{9.55}
\]
Thus, the fluctuation level is much smaller in the short wavelength region $k\lambda_c \gg 1$ than in the long wavelength region $k\lambda_c \ll 1$. This agrees with our intuition, which would predict a high fluctuation level for the weakly damped long wavelength normal modes (Langmuir waves).

It has been shown in an elegant calculation by Rostoker [10] that for a Maxwellian $g(u)$, the exact expression for all wave numbers is

$$W(k) = \frac{T_e}{2} \frac{1}{1 + k^2\lambda_e^2}$$

(9.56)

so that

$$W = \frac{T_e}{2} \int \frac{d\mathbf{k}}{(2\pi)^3} \frac{1}{1 + k^2\lambda_e^2}$$

(9.57)

**EXERCISE** Does (9.56) give the correct limits (9.54) and (9.55)? Is the integral in (9.57) convergent or divergent? What is your physical interpretation of this?

This brings us to the end of this brief chapter on fluctuations and shielding. The test particle technique used here can be used to study the Cerenkov emission of electrostatic waves and their absorption via Landau damping. This is an illustration of the principle of detailed balance. The net result is the steady-state level of electric field fluctuations.

Another application of the principle of detailed balance, in the presence of a background magnetic field, involves synchrotron emission and cyclotron damping.

The principle of detailed balance also applies to the emission of electromagnetic radiation via bremsstrahlung, and its absorption via collisional damping. Since these processes involve the collision of two charged particles, it is not sufficient to use the simple test charge theory that we used for electrostatic fluctuations. Another way to say this is that Langmuir waves are emitted via Cerenkov emission, with $\omega = \mathbf{k} \cdot \mathbf{v}_0$. Electromagnetic waves cannot be emitted in this way in a plasma because their phase speed in a plasma is always greater than the speed of light. For further discussion of these topics, see Refs. [11]-[17].

**REFERENCES**

CHAPTER 10
Weak Turbulence Theory

10.1 INTRODUCTION

Most of the wave phenomena treated in earlier chapters apply to linear waves so small in amplitude that terms which are quadratic in the wave quantities can be discarded. When the wave amplitudes are large enough, the nonlinear terms cannot be discarded. Examples of these nonlinear effects include the particle trapping discussed in Section 6.8, the nonlinear wave equations with soliton solutions introduced in Sections 7.15 and 7.16, and the parametric instabilities treated in Section 7.17. All of these nonlinear effects can be called coherent, since each solution applies to one realization of a plasma and each solution has a unique spatial dependence.

In this chapter, we discuss the solution of nonlinear equations under conditions that can be called turbulent. By this we mean that we seek the time evolution of certain spatially averaged or ensemble-averaged quantities. The averaging process means that we lose information on the detailed spatial variations in each realization of the plasma.

We treat three topics that commonly come under the heading of weak turbulence theory (Refs. [1] to [5]): quasilinear theory, induced scattering, and wave-wave interactions. Other topics such as resonance broadening and strong turbulence theories like the direct interaction approximation are topics of vigorous current research [6], and are beyond the scope of this book.

10.2 QUASILINEAR THEORY

Although it is possible to develop a general framework that includes all aspects of weak turbulence theory, we will take the alternative approach of considering
each kind of interaction separately, in order to understand the physics involved. Crudely, the concept of weak turbulence means that the nonlinearities are small and yield small corrections to linear behavior, whereas strong turbulence means that the nonlinearities are as strong as the linear terms. In *quasilinear theory* [7, 8], the wave amplitudes are considered to be so small that the wave propagation can be treated by the linear theory of Chapter 7. The nonlinear part of quasilinear theory concerns the long-term effect of many waves on the background distribution function.

Consider the bump-on-tail situation. We have seen in Section 6.5 that Langmuir waves are unstable when their phase speeds correspond to regions of the onedimensional distribution function $g(u)$ with a positive slope. The growth rate as given by (6.52) is proportional to the slope of the distribution function $dg(u)/du_\omega$. Thus, at early times when linear theory is valid we have the growth situation displayed in Fig. 10.1. Here we have only indicated regions of positive imaginary frequency $\omega_i(k)$, graphed as a function of the phase speed of a Langmuir wave $v_\varphi \equiv \omega_i/k \approx \omega_e/k$. We know that linear instability cannot go on forever. For one thing, there is only so much energy in the bump, and the waves certainly cannot grow to levels such that the wave energy is larger than the initial particle energy.

As the waves grow, the particles find themselves in a turbulent situation. Thus, a typical particle's orbit, in both real space and velocity space, will be affected by the turbulent electric fields. In particular, particles will diffuse in both real space and velocity space. Consider all of the particles at position $x_0$ with speed $u_0$ at the initial time $t = 0$. In the absence of any electric fields, these particles would have orbits

$$x(t) = x_0 + u_0 t$$

and

$$u(t) = u_0$$

![Fig. 10.1](image)

Fig. 10.1 Initial bump-on-tail distribution function, and corresponding region of positive growth rate $\omega_i(k)$. 
for all times according to Vlasov theory. In the presence of the turbulent electric fields, the particles are accelerated. Because the fields are turbulent, the acceleration is not constant but is random, being alternately positive and negative. Thus, a typical particle will perform a random walk in velocity space. As with all random walk processes, this implies a diffusion of particles in velocity space (see Appendix B). While all the particles described by (10.1) and (10.2) will experience the same fields and thus will have the same speed \( u(t) \) at time \( t \), particles starting at a neighboring point \( x_0 + \Delta \) with speed \( u_0 \) will have a different time history and thus a different speed at time \( t \).

Diffusion tends to spread out the particles in velocity space. Thus, after some time the waves have grown and the particle distribution \( g(u) \) and wave intensity distribution \( I(v_\phi) \) might look as shown in Fig. 10.2. The slope on the distribution function has changed and, thus, the linear growth rate of each wave has changed; since the maximum positive slope is smaller at time \( t \) than at \( t = 0 \), the maximum growth rate is smaller.

Eventually, the particles diffuse so much that the hole between the bump and the background has filled in, and there is no longer a region of positive slope. Then the linear growth rate of the waves is zero, and we have the steady-state situation shown in Fig. 10.3. Of course, this situation is only a steady state in the context of the Vlasov equation. In practice, the waves will eventually decay away due to collisions, and the distribution will eventually become Maxwellian due to collisions.

Let us develop a mathematical framework for these ideas. To do this, we must be a little more clever than if we were simply doing linear theory. This is because we wish to follow changes in the background distribution function on a very long time scale. It would not do to write \( f = f_0 + f_1 \) where \( f_\phi \) is the initial spatially averaged or ensemble averaged background distribution. Then we would have to

---

**Fig. 10.2** Particle distribution and wave intensity distribution after the waves have grown for some time.
include in $f_i$ the difference between the final distribution and the initial distribution. But since such differences are as large as or larger than $f_0$ in the vicinity of the bump, $f_i$ would be as large or larger than $f_0$, and the expansion would break down.

A more successful approach is to separate

$$f(x,v,t) = f_0(v,t) + f_i(x,v,t) \quad (10.3)$$

where

$$f_0(v,t) = \langle f(x,v,t) \rangle_x \quad (10.4)$$

and the $y$ and $z$ dependencies of $f$ have been integrated out. Thus, $f_0$ is the spatially averaged distribution function, and it changes on the slow time scale as the bump diffuses away. The waves are represented by $f_i(x,v,t)$ and, thus, $(f_i)_x = 0$ as given by (10.3) and (10.4). With this separation, we take $f_i \ll f_0$ for all $(x,v,t)$.

Let us now write the Vlasov equation for electrons, assuming the ions are fixed. We have, in one dimension,

$$\partial_t f + v \partial_x f - \frac{e}{m} E \partial_v f = 0 \quad (10.5)$$

and

$$\partial_x E = -4\pi e \int_{-\infty}^{\infty} dv f_i(x,v,t) \quad (10.6)$$

where the spatially averaged electron distribution function $f_0$ cancels the ion contribution to Poisson’s equation (10.6). Next, average (10.5) over space, to obtain

$$\partial_t \langle f \rangle_x + v \left( \frac{\partial f}{\partial x} \right)_x - \frac{e}{m} \left( E \frac{\partial f}{\partial v} \right)_x = 0 \quad (10.7)$$

Our spatial averaging procedure is to integrate over a finite length $-L/2 \leq x \leq L/2$, divide by $L$, and take the limit as $L \to \infty$. The first term in (10.7) is clearly
\[ \partial_t f_0. \] The second term in (10.7) is
\[ \left( \frac{\partial f}{\partial x} \right) \right)_x = \frac{1}{L} \int_{-L/2}^{L/2} dx \frac{\partial f}{\partial x} = \frac{1}{L} \left[ f\left( x = \frac{L}{2} \right) - f( x = -\frac{L}{2} ) \right] \] (10.8)

where \( \lim_{L \to \infty} \) is always implied when we write \( 1/L \), and where we have assumed that \( f(x, u, t) \) is a smooth, well-behaved function. The third term in (10.7) is simplified by using the assumption that \( \langle E \rangle \) is zero; this is because we take the electric field to be produced by \( f_1 \) inside the plasma volume, with no component of \( E \) being produced by capacitor plates at \( x \to \pm \infty \). Then
\[ \left( E \frac{\partial f}{\partial v} \right)_x = \left( E \frac{\partial f_0}{\partial v} \right)_x + \left( E \frac{\partial f_1}{\partial v} \right)_x \]
\[ = \langle E \rangle \frac{\partial f_0}{\partial v} + \left( E \frac{\partial f_1}{\partial v} \right)_x \]
\[ = \left( E \frac{\partial f_1}{\partial v} \right)_x \] (10.9)

where \( f_0(v, t) \) can be removed from the averaging bracket because it is not a function of \( x \). Equation (10.7) then reads
\[ \partial_t f_0(v, t) = \frac{e}{m} \left( E \frac{\partial f_1}{\partial v} \right)_x \] (10.10)

Equation (10.10) is the nonlinear part of quasilinear theory; \( f_0 \) is changing because of the product of \( E \) and \( f_1 \), which is a second order quantity.

The remainder of quasilinear theory is completely linear. The Vlasov equation (10.5) is linearized using \( f_1 \ll f_0 \), and with the help of Poisson’s equation (10.6) a dispersion relation is obtained. This development is precisely as in Section 6.4, and we obtain the normal mode Langmuir wave frequencies for \( k > 0 \), adapted from (6.52),
\[ \omega(k, t) = \omega_0 \left( 1 + \frac{3}{2} k^2 \lambda_b^2 \right) + i \frac{\pi}{2} \omega_m^2 \frac{e^2}{m} d_u g(u, t) |_{u/k} \] (10.11)

where \( g(u, t) = (1/n_0) f_0(u, t) \). Thus, the linear Langmuir waves evolve with complex frequency as given by (10.11), while the background distribution evolves according to the nonlinear equation (10.10).

Consistent with this ordering, we wish to evaluate the nonlinear term on the right of (10.10) by inserting the linear form of \( f_1 \). We consider the linear waves to consist of a spectrum of right-going waves with different wave numbers; each of these waves has its normal mode frequency \( \omega(k) \) given by (10.11). Thus, the real electric field is
\[ E(x, t) = \int_{-\infty}^{\infty} dk E(k, t) e^{ikx} = \int_{-\infty}^{\infty} dk \tilde{E}(k, t) e^{-i\omega(k)t} + ikx \] (10.12)
where the Fourier transform conventions are given by (5.11) and (5.12). Now \( E(x,t) \) must be real, and in order for it to be real, the component at each wave number (the part at \( k = |k| \) plus the part at \( k = -|k| \)) must be real. Thus, the elementary properties of Fourier transforms imply
\[
\omega_i(-k) = -\omega_i(k)
\]
and
\[
\tilde{E}(k,t) = \tilde{E}^*(-k,t)
\]
The latter implies that \( E(k,t) = E^*(-k,t) \) and \( \omega_i(-k,t) = \omega_i(k,t) \).

**EXERCISE** Demonstrate these results.

The perturbed distribution function \( f_i(x,v,t) \) can also be written in the form (10.12), as
\[
f_i(x,v,t) = \int_{-\infty}^{\infty} dk \ f_i(k,v,t)e^{ikx}
\]
\[
= \int_{-\infty}^{\infty} dk \ \tilde{f}_i(k,v,t)e^{-i\omega(k)t+ikx}
\]
(10.15)
The relation between \( f_i(k,v,t) \) and \( E(k,t) \) is as usual obtained by linearizing the Vlasov equation (10.5), with the assumed dependence \( [-i\omega(k)t + ikx] \), to obtain
\[
f_i(k,v,t) = \frac{-e/m}{i[\omega(k,t) - kv]} \partial_v f_0(v,t)E(k,t)
\]
(10.16)
In the right side of (10.10), we can move the velocity derivative outside the brackets since \( E(x,t) \) does not depend on velocity. We are thus interested in the quantity
\[
\langle E f_i \rangle_x = \frac{1}{L} \int_{-L/2}^{L/2} dx \ E(x,t) f_i(x,v,t)
\]
\[
= \frac{1}{L} \int_{-L/2}^{L/2} dx \ \int dk \ f_i(k)e^{ikx} \int dk' \ E(k')e^{ik'x}
\]
\[
= \frac{1}{L} \int dk \ f_i(k) \int dk' \ E(k') \int_{-L/2}^{L/2} dx \ e^{i(k+k')x}
\]
(10.17)
Equation (10.17) can be simplified by using the standard formula
\[
\lim_{L \to \infty} \int_{-L/2}^{L/2} dx \ e^{iax} = 2\pi \delta(a)
\]
(10.18)
The right-most integral in (10.17) thus becomes \( 2\pi \delta(k + k') \), upon which the \( k' \) integration is trivial, and we obtain
\[
\langle E f_i \rangle_x = \frac{2\pi}{L} \int dk \ E(-k) f_i(k)
\]
\[
= \frac{2\pi}{L} \int dk \ E(-k) \left[ \frac{ie}{m} \frac{1}{\omega - kv} \partial_v f_0 \right] E(k)
\]
(10.19)
where (10.16) has been used. Inserting (10.19) in (10.10) we have

$$\partial_t f_0 (v,t) = - \frac{e^2}{m^2} \frac{2\pi}{L} \partial_v \int_{-\infty}^{\infty} dk \frac{E(-k)E(k)}{i(\omega - kv)} \frac{\partial_v f_0 (v,t)}{i(\omega - kv)} \quad (10.20)$$

With the result below (10.14) this becomes

$$\partial_t f_0 (v,t) = - \frac{e^2}{m^2} \frac{2\pi}{L} \partial_v \left\{ \left[ \int_{-\infty}^{\infty} dk \frac{|E(k)|^2}{i(\omega - kv)} \right] \partial_v f_0 (v,t) \right\} \quad (10.21)$$

Equation (10.21) can be simplified by defining the so-called spectral density $\epsilon(k)$ of the electric field. The natural definition of this quantity is

$$\epsilon(k) \equiv \frac{1}{4L} |E(k)|^2 \quad (10.22)$$

Then the average electric field energy density is

$$\left(\frac{E^2}{8\pi}\right)_x = \frac{1}{8\pi L} \int_{-L/2}^{L/2} dx \ E^2(x)$$

$$= \frac{1}{8\pi L} \int_{-L/2}^{L/2} dx \ \int dk \ E(k) e^{ikx} \int dk' \ E(k') e^{ik'x}$$

$$= \frac{1}{8\pi L} \int dk \ E(k) \int dk' \ E(k') \int_{-L/2}^{L/2} dx \ e^{i(k+k')x}$$

$$= \frac{1}{4L} \int dk \ E(k) E(-k)$$

$$= \frac{1}{4L} \int dk \ |E(k)|^2$$

$$= \int_{-\infty}^{\infty} dk \ \epsilon(k) \quad (10.23)$$

which shows that $\epsilon(k)$ is the wave energy density, per unit interval of wave number space.

With the definition (10.22), Eq. (10.21) reads

$$\partial_t f_0 (v,t) = - \frac{8\pi e^2}{m^2} \partial_v \left\{ \left[ \int_{-\infty}^{\infty} dk \ \frac{\epsilon(k)}{i(\omega - kv)} \right] \partial_v f_0 (v,t) \right\} \quad (10.24)$$

This equation is in the form of a diffusion equation,

$$\partial_t f_0 (v,t) = \partial_0 [D(v,t) \partial_v f_0 (v,t)] \quad (10.25)$$

with

$$D(v,t) \equiv - \frac{8\pi e^2}{m^2} \int_{-\infty}^{\infty} dk \ \frac{\epsilon(k,t)}{i[\omega(k,t) - kv]} \quad (10.26)$$

Since $\partial_0 \epsilon(k) = \omega \tilde{E}(k)$, the spectral density (10.22) must satisfy

$$\partial_t \epsilon(k,t) = 2\omega(k,t) \epsilon(k,t) \quad (10.27)$$
or

$$
\epsilon(k,t) = \epsilon(k,t = 0) \exp \left[ 2 \int_0^t \omega_i(k,t') \, dt' \right] \tag{10.28}
$$

where \( \omega_i(k,t) \) is determined from the normal mode frequency (10.11). Given initial conditions \( f_0(v,t = 0) \) and \( \epsilon(k,t = 0) \), Eqs. (10.25), (10.26) and (10.28) provide a complete description of the time evolution of the system. For the bump-on-tail problem, the evolution is as described in the beginning of this section, with diffusion eventually resulting in a flat distribution function \( f_0(v,t \to \infty) \).

There are several useful forms of the diffusion coefficient \( D(v,t) \) in (10.26). Since \( f_0 \) is real, it must be true that \( D(v,t) \) is real. The integrand of (10.26) is of the form

$$
\frac{-i \epsilon(k)}{(\omega - kv)} = \frac{-i \epsilon(k)}{\omega_i + i \omega_i - kv} = \frac{-i \epsilon(k) [\omega_r - kv - i \omega_i]}{(\omega_r - kv)^2 + \omega_i^2} \tag{10.29}
$$

Using the symmetries (10.13), and the fact that \( \epsilon(-k) = \epsilon(k) \), we see that the imaginary part of (10.29) is odd in \( k \) and, thus, vanishes upon integration in (10.26).

**EXERCISE** Verify the last statement.

We have left

$$
D(v,t) = \frac{8 \pi e^2}{m^2} \int_{-\infty}^{\infty} dk \frac{\epsilon(k,t) \omega_i(k,t)}{[\omega_r(k,t) - kv]^2 + [\omega_i(k,t)]^2} \tag{10.30}
$$

In the limit of very tiny \( \omega_i \), the integrand in (10.30) takes a form \( \sim \delta(\omega_r - kv) \), and we find

$$
D(v,t) = \frac{16 \pi^2 e^2}{m^2} \frac{1}{v} \epsilon(k = \omega_i/v,t) \tag{10.31}
$$

**EXERCISE** Verify (10.31) by going back to (10.26) and using the formula

$$
\lim_{\epsilon \to 0} \frac{1}{x - i \epsilon - a} = P \left( \frac{1}{x - a} \right) + \pi i \delta(x - a) \tag{10.32}
$$

To show that the \( P(\ ) \) part vanishes, and the constant in (10.31) comes out right, be careful to count all of the places where \( x = a \). The plus sign is chosen because we use the equivalent of a Landau contour in (10.26), as demanded by a proper treatment of the initial value problem.

Thus, (10.31) shows that the diffusion of particles with speed \( v \) is caused by waves with phase speeds \( \omega_i/k = v \). This is resonant behavior, where particles interact strongly with those waves with which they are resonant, with \( \omega_i = kv \). In the linear theory, it is the resonant particles that cause linear Landau growth or damping, as shown in (10.11). In the quasilinear theory, it is the resonant particles that are diffused because of the wave fields.
Quasilinear theory, with its simplicity and straightforward application to magnetized plasmas, has seen and continues to see a great deal of use in both fusion and astrophysical applications. In the next section, we shall proceed to consider another aspect of weak turbulence theory.

### 10.3 INDUCED SCATTERING

In the previous section, we considered one aspect of weak turbulence theory, the nonlinear diffusion of particles due to the presence of many waves. We now wish to consider another aspect of weak turbulence theory, the nonlinear coupling of one wave to another wave through the background particles. This is called *induced scattering* [9], induced scattering off ions, induced scattering off the polarization clouds of ions, and nonlinear Landau damping. All of these terms refer to the same process; the last expression is somewhat unfortunate, as this process has nothing to do with the nonlinear stage of linear Landau damping, as discussed in Section 6.8.

In linear Landau damping or growth, the important concept is a resonance between one wave and one particle, satisfying the linear resonance condition

$$\omega = kv$$  \hspace{1cm} (10.33)

such that the particle velocity \(v\) equals the wave phase velocity \(\omega/k\). In induced scattering, the important concept is a resonance between two waves and one particle, satisfying the resonance condition

$$\omega_1 - \omega_2 = (k_1 - k_2)v$$  \hspace{1cm} (10.34)

such that

$$v = \frac{\omega_1 - \omega_2}{k_1 - k_2}$$  \hspace{1cm} (10.35)

that is, the particle velocity equals the velocity of the *beat* of two waves.

Consider a particle in the presence of two real waves. Then Newton’s force law says

$$m\ddot{x} = qE_1 \exp(-i\omega_1 t + ik_1 x) + qE_2 \exp(-i\omega_2 t + ik_2 x) + \text{c.c.}$$  \hspace{1cm} (10.36)

where all fields are real so that the complex conjugate must be added to the right side of (10.36). Equation (10.36) is a very nonlinear equation for the particle orbit \(x(t)\). If the fields \(E_1, E_2\) are not too large, we can solve (10.36) perturbatively. We have

$$x = x_0 + x_1$$  \hspace{1cm} (10.37)

where

$$x_0 = vt$$  \hspace{1cm} (10.38)

is the orbit of the particle in the absence of the fields. Inserting (10.37) into (10.36) and expanding the exponents, we find

$$m\ddot{x}_1 = qE_1 \exp(-i\omega_1 t + ik_1 v_0 t + ik_1 x_1)$$

+ \(qE_2 \exp(-i\omega_2 t + ik_2 v_0 t + ik_2 x_1) + \text{c.c.}\)

= \(qE_1 \exp(-i\omega_1 t + ik_1 v_0 t)(1 + ik_1 x_1)\)

+ \(qE_2 \exp(-i\omega_2 t + ik_2 v_0 t)(1 + ik_2 x_1) + \text{c.c.}\)  \hspace{1cm} (10.39)
First, ignore $x_1$ on the right of (10.39). Then the lowest order solution to $x_1$ comes from integrating (10.39) twice with respect to time. We find

$$x_1(t) \simeq \frac{q}{m} \frac{E_1 \exp(-i\omega_1 t + ik_1 v_0 t)}{(\omega_1 - k_1 v_0)^2}$$

$$\quad - \frac{q}{m} \frac{E_2 \exp(-i\omega_2 t + ik_2 v_0 t)}{(\omega_2 - k_2 v_0)^2} + \text{c.c.} \quad (10.40)$$

Inserting this lowest order solution to $x_1$ in the right side of (10.39), we obtain 20 terms, or

$$\ddot{x}_1 = -\frac{(q^2/m^2)ik_1E_1E_2^*}{(\omega_1 - k_2 v_0)^2} \exp[-i(\omega_1 - \omega_2)t + i(k_1 - k_2)v_0 t] + \text{(19 terms)} \quad (10.41)$$

If the resonance condition (10.34),

$$(\omega_1 - \omega_2) - (k_1 - k_2)v_0 = 0 \quad (10.42)$$

is satisfied, we see that (10.41) will have at least one force term that is constant in time. Thus, a particle with initial velocity $v_0$ as given by (10.35) can interact very strongly with two waves [3].

A plasma contains not one but many particles. As a specific problem, we consider the interaction of two Langmuir waves $E_1$ and $E_2$, with a low frequency disturbance. We assume that the low frequency disturbance is dominated by details of the ion distribution, with the electrons simply supplying the charge to almost neutralize the low frequency disturbance; that is, we invoke quasineutrality of the low frequency disturbance. Then we can use fluid theory to describe the electrons; from Chapter 7 we have

$$m_e n_e \partial_x V_e + m_i n_i V_e \partial_x n_e = -\gamma_e T_e \partial_x n_e - e n_e E \quad (10.43)$$

$$\partial_t n_e + \partial_x (n_e V_e) = 0 \quad (10.44)$$

and

$$\partial_x E = -4\pi e n_e \quad (10.45)$$

where we shall only use Poisson’s equation to describe high frequency electron oscillations. The ions are described by the Vlasov equation with $f_i(v) = f_0(v) + f_i(v)$,

$$\partial_t f_1 + v \partial_x f_1 + \frac{e}{m_i} E \partial_v f_0 = 0 \quad (10.46)$$

where $v \equiv v_x$ and $f_i$ has already been integrated over $v_x$ and $v_i$. Although the theory we are performing is not a linear one, we have ignored the term involving $\partial_v f_i$ in (10.46). Thus, the theory is limited to those regimes where $\partial_v f_1 \ll \partial_v f_0$ for all ion velocities of interest.

The high frequency fields are given by $E_1 \exp(-i\omega_1 t + ik_1 x) + E_2 \exp(-i\omega_2 t + ik_2 x) + \text{c.c.}$ We consider $E_1$ to be a relatively large wave with a real frequency $\omega_1$. The field $E_2$ is considered to be a tiny wave, which can use the ions
to drain energy from the large field $E_1$; hence the term induced scattering. The frequency $\omega_2$ is therefore complex, with a positive imaginary part describing its growth. The low frequency response is described by a density perturbation $n_3 \exp (-i\omega_3 t + ik_3 x) + c.c. \text{ We assume that the frequency matching condition}$

$$\omega_1 = \omega_2 + \omega_3^*$$

(10.47)

and the wave number matching condition

$$k_1 = k_2 + k_3$$

(10.48)

are both satisfied. Here, $\omega_1$, $k_1$, $k_2$, and $k_3$ are real while $\omega_2$ and $\omega_3$ are complex with the same imaginary part. We note that

$$\omega_1 \approx \omega_2 >> \omega_3,$$

(10.49)

For the high frequency modes, we have in mind waves that would be normal modes (Langmuir waves) of the plasma in the absence of the coupling. The low frequency mode, however, is a disturbance that would be strongly damped in the absence of the coupling. For example, it could be an ion-acoustic mode in an equal temperature plasma, which is strongly Landau damped by the ions. By contrast, the parametric instability theory of Section 7.17 is valid when $T_e >> T_i$ so that ion-acoustic waves are not strongly damped.

We first treat the behavior at frequency $\omega_2$. From Eq. (10.43), we write all terms that vary as $\exp(-i\omega_2 t + ik_3 x)$, given the matching conditions (10.47) and (10.48). We keep linear terms and second order terms, but we discard terms that are third order in small quantities. Dividing (10.43) by $m_e n_e$, we have for high frequency motions

$$\partial_t V_e + V_e \partial_x V_e = -\gamma_e \frac{T_e}{m_e n_0} \partial_x n_e - \frac{e}{m_e} E$$

(10.50)

where nonlinearities in the pressure term (which would multiply the small $k^2\lambda_e^2$ correction to the Langmuir dispersion relation) have been ignored. The appropriate terms are

$$-i\omega_2 v_2 - ik_3 v_3^* v_1 + ik_1 v_1 v_3^* = -3i k_2 \frac{T_e}{m_n n_0} n_2 - \frac{e}{m_e} E$$

(10.51)

where $v_2$ is the component of $V_e$ with time dependence $\sim \exp(-i\omega_2 t)$, etc. Similarly, the terms in the continuity equation (10.44) that vary as $\exp(-i\omega_2 t + ik_3 x)$ are

$$-i\omega_2 n_2 + ik_2 (n_0 v_2 + n_1 v_1^* + n_3^* v_1) = 0$$

(10.52)

**EXERCISE** Verify that all the appropriate terms appear in (10.51) and (10.52).

Equation (10.51) can be solved for $v_2$, and the result inserted in (10.52). We find

$$-i\omega_2 n_2 = -i k_2 \left[ n_1 v_3^* + n_3^* v_1 - n_0 \frac{k_3}{\omega_2} v_3^* v_1 \right.

\left. + \frac{n_0 k_1}{\omega_2} v_1 v_3^* + \frac{3k_2 (T_e/m_e) n_2}{\omega_2} + \frac{n_0 e}{i\omega_m} E \right]$$

(10.53)
We next wish to discard the sum of terms (1), (2), and (3). This sum is of the form

\[ \text{(1) + (2) + (3) = } v_3^* \left( n_1 - n_0 \frac{k_3}{\omega_2} v_1 + n_0 \frac{k_1}{\omega_2} v_1 \right) \]  

(10.54)

To lowest order, the continuity equation (10.44) gives

\[ n_1 = n_0 \frac{k_1}{\omega_1} v_1 \approx n_0 \frac{k_1}{\omega_2} v_1 \]  

(10.55)

where the last form is valid since \( \omega_1 \approx \omega_2 \). Equation (10.54) becomes

\[ \text{(1) + (2) + (3) = } \frac{v_3^* v_1 n_0}{\omega_2} (k_1 - k_3 + k_1) \]  

\[ = \frac{v_3^* v_1 n_0}{\omega_2} (k_1 + k_2) \]  

(10.56)

However, this is much smaller than term (4),

\[ \text{(4) = } n_3^* v_1 = n_0 v_3^* v_1 \frac{k_3}{\omega_3^*} \]  

(10.57)

where the last form follows from the lowest order continuity equation for \( n_3^* \). Equation (10.57) is much larger than Eq. (10.56) because \( |\omega_3^*| \ll |\omega_2| \), provided the wave numbers are of the same order. Thus, in (10.53) we neglect terms (1), (2), and (3) compared to term (4) to obtain

\[ \left[ -i \frac{3k_2^2(T/m_e)}{\omega_2} - \frac{\omega_e^2}{i\omega_2} \right] n_2 = -i k_3 n_3^* v_1 \]  

(10.58)

where \( E_2 \) in (10.53) is eliminated using the component of Poisson’s equation varying at the frequency \( \omega_2 \). Multiplying by \( i\omega_2 \) one finds

\[ (\omega_2^2 - \omega_e^2 - 3k_2^2 v_e^2) n_2 = \omega_2 k_3 n_3^* v_1 \]  

(10.59)

If (10.59) were linearized by neglecting the right side, the remainder would yield the familiar Langmuir wave dispersion relation. Separating the factor \( \omega_2^2 - 3k_2^2 v_e^2 \) on the left, we obtain

\[ (\omega_2^2 - 3k_2^2 v_e^2) \epsilon(\omega_2, k_3) n_2 = \omega_2 k_3 n_3^* v_1 \]  

(10.60)

where \( \epsilon(\omega_2, k_3) \) is the high frequency dielectric function

\[ \epsilon(\omega, k) = 1 - \frac{\omega_e^2}{\omega^2 - 3k_2^2 v_e^2} \]  

(10.61)

Having obtained the high frequency equation (10.60), we are one-half done with our derivation. We must now obtain a low frequency equation for \( n_3^* \). Recall that to lowest order, \( v_1 \) is obtained from the force equation

\[ m_e \dot{v}_1 = -eE_1 \]  

(10.62)

or

\[ v_1 = \frac{eE_1}{i\omega_1 m_e} \]  

(10.63)
so that $v_1$ in (10.60) is determined by (10.63), with $\omega_1$ real as discussed above (10.49).

Let us derive the low frequency part. We intend to enforce quasineutrality, $n_3 = n_{e3} \approx n_{i3}$. For the electrons, the components of the force equation (10.43) varying as $\exp(-i\omega_3 t + ik_3 x)$ are, dividing first by $m_e n_e$ and ignoring nonlinearities in the pressure term,

$$-i\omega_3 v_1 - v_1 i k_3 v_2^* + i k_1 v_1 v_2^* = -i \frac{T_e}{n_0 m_e} k_3 n_3 - \frac{e}{m_e} E_3$$  \hspace{1cm} (10.64)

where we have chosen $\gamma_e = 1$ for low frequency motions. We neglect $-i\omega_3 v_3$ because $\omega_3$ is small, and use $k_1 = k_2 = k_3$ to obtain

$$E_3 = -\frac{T_e}{en_0} i k_3 n_3 - \frac{im_e k_3}{e} v_1 v_2^*$$  \hspace{1cm} (10.65)

From the lowest order continuity equation, $v_2^* = (\omega_2^*/k_2)(n_2^*/n_0)$, therefore,

$$E_3 = -\frac{T_e}{en_0} i k_3 n_3 - \frac{im_e k_3}{n_0 e} \frac{k_3}{k_2} v_1 \omega_2^* n_2^*$$  \hspace{1cm} (10.66)

The low frequency ion response is given by the Vlasov equation (10.46), which yields

$$f_{13} = \frac{-(e/m_i)}{-i(\omega_3 - k_3 v)} \frac{-i (e/m_i)}{i(\omega_3 - k_3 v)} \partial_v f_0$$  \hspace{1cm} (10.67)

where $f_{13}$ is the perturbed ion distribution function at frequency $\omega_3$ and $f_0$ is the zero order ion distribution function. The low frequency density disturbance is

$$n_3 = \int_{-\infty}^{\infty} dv f_{13} = E_3 \int_{-\infty}^{\infty} dv \frac{(e/m_i)}{i(\omega_3 - k_3 v)} \partial_v f_0$$

$$= \left( -\frac{T_e i k_3 n_3}{en_0} - \frac{im_e k_3 v_1 \omega_2^* n_2^*}{n_0 e k_2} \right) \int_{-\infty}^{\infty} dv \frac{(e/m_i)}{i(\omega_3 - k_3 v)} \partial_v f_0$$  \hspace{1cm} (10.68)

Defining

$$W \equiv k_3 T_e \int_{-\infty}^{\infty} dv \frac{\partial_v f_0}{\omega_3 - k_3 v}$$  \hspace{1cm} (10.69)

we solve (10.68) for $n_3$ to obtain

$$n_3 = -\frac{m_e v_1 \omega_2^* n_2^*}{k_3 T_e} \frac{W}{1 + W}$$  \hspace{1cm} (10.70)

for the low frequency density perturbation $n_3$.

We finally insert the complex conjugate of (10.70) into the high frequency equation (10.60) to obtain an equation with $n_2$ on both sides. Cancelling $n_2$, we have

$$(\omega_2^* - 3 k_2^2 v_2^*) (\omega_2, k_2) = -\frac{m_e}{T_e} |v_1|^2 \omega_2^2 \frac{W^*}{1 + W^*}$$  \hspace{1cm} (10.71)

which is a nonlinear dispersion relation for the complex frequency $\omega_2$. Ignoring the small thermal correction $3 k_2^2 v_2^*$ on the left, we can divide out $\omega_2^2$ on both sides.
Then defining the thermal speed \( v_\text{e}^2 \equiv T_\text{e} / m_\text{e} \), we have
\[
\epsilon_{NL} \equiv \epsilon_\text{NL}(k_1, k_2) + \frac{|v_1|^2}{v_\text{e}^2} \frac{W^*}{1 + W^*} = 0
\]
(10.72)

where we have introduced the nonlinear dielectric function \( \epsilon_{NL} \). If the fixed electric field \( E_1 \to 0 \), then \( v_1 = eE_1 / m_\text{e} w_1 \to 0 \), and we regain the linear Landau dispersion relation \( \omega(k_2) \).

With \( v_1 \) finite, we have the possibility of instability. We call \( \epsilon_{NL} \) a nonlinear dispersion relation because it contains the square of the field \( E_1 \sim v_1 \). However, with \( v_1 \) considered a constant, we can treat \( \epsilon_{NL} \) in the same fashion as we did linear dielectric functions in Section 6.5. Recall that for small instability \( |\omega_2| \ll |\omega_1| \), we have from (6.42) and (6.43),
\[
\epsilon_\text{r}(\omega_2) = 0
\]
(10.73)

and
\[
\omega_{2i} = \frac{-\epsilon_\text{r}(\omega_2)}{\partial \epsilon_\text{r}/\partial \omega|_{\omega_1}}
\]
(10.74)

The imaginary part of the dielectric function (10.72) comes from \( W \), given in (10.69). Evaluating \( W \) using the Landau contour for \( |\omega_3| \ll |\omega_1| \), we have
\[
W = W_\text{r} - \frac{T_\text{e}}{m \pi n_0} \pi i \partial_v f_0|_{\omega_1/k},
\]
(10.75)

where the real part of \( W, W_\text{r} \), involves a principal value integral that we shall not bother to evaluate.

We require the imaginary part of \( \epsilon_{NL} \) in (10.72), which is proportional to
\[
\text{Im}[W^*/(1 + W^*)] = -W_\text{r}/(1 + W_\text{r})^2
\]
(10.76)

where \( W_\text{r} \) has been treated as a small quantity and terms quadratic in \( W_\text{r} \) have been ignored.

**EXERCISE** Verify (10.76).

Then
\[
\text{Im}(\epsilon_{NL}) = -\frac{|v_1|^2}{v_\text{e}^2} \frac{W_\text{r}}{(1 + W_\text{r})^2}
\]
\[
= \frac{1}{(1 + W_\text{r})^2} \frac{|v_1|^2}{v_\text{e}^2} \frac{T_\text{e}}{m \pi n_0} \partial_v f_0|_{\omega_1/k},
\]
(10.77)

For \( \partial \epsilon_\text{r}/\partial \omega|_{\omega_1} \) in (10.74), we can use the dielectric function \( \epsilon = 1 - \omega_\text{e}^2/\omega^2 \) to obtain
\[
\frac{\partial \epsilon_\text{r}}{\partial \omega|_{\omega_1} \approx \frac{2}{\omega_\text{e}}}
\]
(10.78)
Equation (10.78) ignores the thermal correction and the *nonlinear frequency shift* that would be given by (10.72). Then the growth rate (10.74) is

\[
\omega_{3i} = \omega_{2i} = -\frac{1}{(1 + W_r)^2} \frac{\omega_e}{2} \left| \frac{v_{1x}}{v_e} \right|^2 \frac{T_e \pi}{m_i n_0} \partial_v f_0 |_{\omega_{i} / k_i}
\]  

(10.79)

Notice that the derivative \( \partial_v f_0 \) is evaluated at

\[
v = \frac{\omega_{3r}}{k_3} = \frac{\omega_1 - \omega_{2r}}{k_1 - k_2}
\]  

(10.80)

which is the phase speed of the *beat* between \( \omega_1 \) and \( \omega_{2r} \). This reinforces our notion of a nonlinear resonance between two waves and one particle.

The growth rate (10.79) is positive when the slope \( \partial_v f_0 \) is negative. Thus, the waves \( E_2 \) that grow fastest are the ones whose beat with \( E_1 \) falls near the ion thermal speed for Maxwellian ions (Fig. 10.4).

There is a very close relation between the *induced scattering* considered here, involving two high frequency waves and the ions, and the *parametric decay instability* discussed in Section 7.17. The former is more appropriate when \( T_\epsilon \approx T_i \), and the beat phase velocity is likely to fall in the body of the ion distribution. The latter is inappropriate when \( T_\epsilon \approx T_i \) because the low frequency wave equation is an undamped ion-acoustic wave in the absence of nonlinear coupling; when \( T_\epsilon \approx T_i \) ion-acoustic waves are strongly Landau damped by ions. The latter is more appropriate when \( T_\epsilon \gg T_i \) and ion-acoustic waves are undamped. In the next section, we introduce a statistical approach for the case \( T_\epsilon \gg T_i \).

![Fig. 10.4](image)

**Fig. 10.4** For a given finite amplitude Langmuir wave with frequency \( \omega_1 \) and wave number \( k_1 \), the fastest growing Langmuir waves due to induced scattering are those with frequency \( \omega_{2r} \), wave number \( k_2 \), such that \( \frac{\omega_1 - \omega_{2r}}{k_1 - k_2} \approx v_i \).
10.4 WAVE-WAVE INTERACTIONS

In the preceding two sections, we have discussed two important aspects of weak turbulence theory. The first was quasilinear theory, which involves the linear wave-particle interaction characterized by the expression

$$\omega = \mathbf{k} \cdot \mathbf{v}$$  \hspace{1cm} (10.81)

The second was induced scattering, which involves the nonlinear wave-particle interaction characterized by the expression

$$\omega_1 - \omega_2 = (\mathbf{k}_1 - \mathbf{k}_2) \cdot \mathbf{v}$$  \hspace{1cm} (10.82)

In the first case, a particle is resonant with one wave; its speed is equal to the phase speed of the wave in the direction of the particle’s velocity,

$$|\mathbf{v}| = \omega/k_\parallel$$  \hspace{1cm} (10.83)

where $k_\parallel = \mathbf{k} \cdot \mathbf{v}/v$. In the second case, a particle is resonant with the beat between two waves; its speed is equal to the phase speed of the beat between the two waves in the direction of the particle’s velocity,

$$|\mathbf{v}| = \frac{\omega_1 - \omega_2}{(\mathbf{k}_1 - \mathbf{k}_2)_\parallel}$$  \hspace{1cm} (10.84)

where

$$(\mathbf{k}_1 - \mathbf{k}_2)_\parallel \equiv [(\mathbf{k}_1 - \mathbf{k}_2) \cdot \mathbf{v}]/v$$  \hspace{1cm} (10.85)

In this section, we wish to consider a third important aspect of weak turbulence theory, that of nonlinear wave-wave interaction. We shall find that this interaction is characterized by a frequency matching condition

$$\omega_1 = \omega_2 + \omega_3$$  \hspace{1cm} (10.86)

and by a wave number matching condition

$$\mathbf{k}_1 = \mathbf{k}_2 + \mathbf{k}_3$$  \hspace{1cm} (10.87)

For wave-wave interactions, we assume that resonant particle interactions (both linear and nonlinear) are not important, so that the conditions (10.86) and (10.87) do not involve a particle velocity.

We shall illustrate the ideas of wave-wave interaction by using the Zakharov equations discussed in Section 7.16. Recall that this equation describes the nonlinear coupling between linear Langmuir waves and linear ion-acoustic waves. Thus, this approach is valid for a plasma with $T_e \gg \gg T_i$, when we know that ion-acoustic waves exist. For the case $T_e \approx T_i$, there are no undamped ion-acoustic modes, and we cannot use the wave-wave interaction ideas to be developed here. Rather, when $T_e \approx T_i$ we would expect the nonlinear wave-particle interactions (induced scattering) of the previous section to be the dominant nonlinear interaction between high frequency electron waves and low frequency ion fluctuations.

The physical interaction discussed here is the same as the physical interaction that yielded the parametric decay instability of Section 7.17. However, in that case
we considered a single finite-amplitude Langmuir wave that decays into one other Langmuir wave and one ion-acoustic wave. By contrast, here we consider a broad spectrum of Langmuir waves that evolves according to the nonlinear physics contained in the Zakharov equations. Our approach is a statistical one, so that we predict the evolution of the waves in an ensemble of systems rather than the evolution of the waves in a single system.

The Zakharov equations (7.329) and (7.330) are

\[ i \partial_t E(x,t) + \partial_x^2 E = nE \]  
\[ \partial_t^2 n(x,t) - \partial_x^2 n = \partial_x^2 |E|^2 \]  

The spatial Fourier transform of (10.88) is

\[ i \partial_t E(k,t) - k^2 E = \int_{-\infty}^{\infty} \frac{dx}{2\pi} e^{-ikx} n(x,t)E(x,t) \]
\[ = \int_{-\infty}^{\infty} \frac{dx}{2\pi} e^{-ikx} \left[ \int_{-\infty}^{\infty} dk' n(k',t)e^{ik'x} \right] \]
\[ \times \left[ \int_{-\infty}^{\infty} dk'' E(k'',t)e^{ik''x} \right] \]
\[ = \int_{-\infty}^{\infty} dk' n(k',t) \int_{-\infty}^{\infty} dk'' E(k'',t) \int_{-\infty}^{\infty} \frac{dx}{2\pi} e^{i(k-k'-k'')x} \delta(k-k'-k'') \]
\[ = \int_{-\infty}^{\infty} dk' n(k',t)E(k-k',t) \]

so

\[ i \partial_t E(k,t) - k^2 E(k,t) = \int_{-\infty}^{\infty} dk' n(k',t)E(k-k',t) \]  

Note that the wave number matching condition \( k = k' + k'' \) has already appeared in the argument of the \( \delta \)-function in (10.90).

Suppose we look at the linear limit of (10.91). We ignore the nonlinear right side, and find

\[ i \partial_t E(k,t) = k^2 E(k,t) \]

so

\[ E(k,t) = E(k,t = 0) \exp(-ik^2 t) \]

Defining

\[ \omega_l(k) = k^2 \]

we have

\[ E(k,t) = E(k,t = 0) \exp[-i\omega_l(k)t] \]

where the subscript \( l \) in (10.94) means “Langmuir.” Recall that the Zakharov equations are obtained by factoring out the high frequency time dependence exp
\((-i\omega, t);\) if we put this time dependence back in and change back to dimensional variables, we would find that (10.94) becomes

\[
\tilde{\omega}_j(\tilde{k}) = \omega_e \left( 1 + \frac{3}{2} \tilde{k}^2 \lambda_e^2 \right) \tag{10.96}
\]

where \(\tilde{k}\) is the dimensional wave number and \(\tilde{\omega}_j\) is the dimensional frequency; this is just our old friend the Langmuir wave dispersion relation.

**EXERCISE** Why is \(\omega^2 = \omega_e^2 + 3k^2v_e^2\) the same as \(\omega = \omega_e \left( 1 + \frac{3}{2} k^2 \lambda_e^2 \right)\) for Langmuir waves?

The idea of weak turbulence theory is to assume that each Langmuir wave approximately obeys its linear solution (10.95). However, the amplitude is allowed to have a slow time variation because of the nonlinear term on the right of (10.91), rather than being an exact constant as in the linear solution (10.95).

Consider next the spatial Fourier transform of (10.89), which is

\[
\partial_t^2 n(k, t) + k^2 n(k, t) = -k^2 \int_{-\infty}^{\infty} \frac{dx}{2\pi} e^{-ikx} E(x, t)E^*(x, t) \\
= -k^2 \int_{-\infty}^{\infty} \frac{dx}{2\pi} e^{-ikx} \left[ \int_{-\infty}^{\infty} dk' e^{ik'x} E(k', t) \right] \\
\times \left[ \int_{-\infty}^{\infty} dk'' e^{-ik''x} E^*(k'', t) \right] \\
= -k^2 \int_{-\infty}^{\infty} dk' E(k', t) \int_{-\infty}^{\infty} dk'' E^*(k'', t) \int_{-\infty}^{\infty} \frac{dx}{2\pi} e^{i(k-k'-k'')x} \delta(k - k' + k'') \tag{10.97}
\]

so

\[
\partial_t^2 n(k, t) + k^2 n(k, t) = -k^2 \int_{-\infty}^{\infty} dk' E(k', t)E^*(k' - k, t) \tag{10.98}
\]

The linear limit of (10.98) is

\[
\partial_t^2 n(k, t) + k^2 n(k, t) = 0 \tag{10.99}
\]

with solution

\[
n(k, t) = A(k) \exp(-ikt) + B(k) \exp(ikt) \tag{10.100}
\]

Since \(n(x, t)\) is real, it must be true that

\[
n(k, t) = n^*(-k, t) \tag{10.101}
\]

**EXERCISE** Prove (10.101).
Then

\[ A(k) = A^*(-k) \]  \hspace{1cm} (10.102)

and

\[ B(k) = B^*(-k) \]  \hspace{1cm} (10.103)

Linear theory tells us that \( A(k) \) and \( B(k) \) are constants in time. Defining

\[ \omega_s^s(k) \equiv k \]  \hspace{1cm} (10.104)

and

\[ \omega_s^s(k) \equiv -k \]  \hspace{1cm} (10.105)

where \( s \) means "sound" (acoustic), we can write (10.100) as

\[ n(k,t) = A(k) \exp [-i \omega_s^s(k)t] + B(k) \exp [-i \omega_s^s(k)t] \]  \hspace{1cm} (10.106)

Note that \( A(k) \) is the amplitude of the right-going ion-acoustic waves \( \omega_s^+ / k = 1 > 0 \) while \( B(k) \) is the amplitude of the left-going ion-acoustic waves \( \omega_s^- / k = -1 < 0 \). The idea of weak turbulence theory is to use the form (10.106) in (10.98), but to allow the coefficients \( A(k,t) \) and \( B(k,t) \) to be slowly varying functions of time. The word "slowly" in this context means slow compared to the terms \( \exp [-i \omega_s^s(k)t] \). (Note that in physical units, the frequencies \( \omega_s^\pm(k) \) are just the frequencies of our old friends the ion-acoustic waves, \( \omega_s^\pm(k) = \pm \tilde{c}_s \).)

Thus, we want to solve equations (10.91) and (10.98) with solutions of the form

\[ E(k,t) = \bar{E}(k,t) \exp [-i \omega(k)t] \]  \hspace{1cm} (10.107)

and

\[ n(k,t) = A(k,t) \exp [-i \omega_s^s(k)t] + B(k,t) \exp [-i \omega_s^s(k)t] \]  \hspace{1cm} (10.108)

where \( \bar{E}(k,t) \), \( A(k,t) \), and \( B(k,t) \) are slowly varying. After we insert these forms into (10.91), the left side becomes

\[ i \partial_t \bar{E}(k,t) - k^2 \bar{E}(k,t) = i \partial_t \bar{E}(k,t) \exp [-i \omega(k)t] \]

\[ + \omega(k)\bar{E}(k,t) \exp [-i \omega(k)t] - k^2 \bar{E}(k,t) \exp [-i \omega(k)t] \]

\[ = i \partial_t \bar{E}(k,t) \exp [-i \omega(k)t] \]  \hspace{1cm} (10.109)

since by (10.94) the last two terms cancel. The entire equation (10.91) becomes

\[ i \partial_t \bar{E}(k,t) \exp [-i \omega(k)t] = \int_{-\infty}^{\infty} dk' \{ A(k',t) \exp [-i \omega_s^s(k')t] \]

\[ B(k',t) \exp [-i \omega_s^s(k')t] \} \cdot \bar{E}(k - k',t) \exp [-i \omega(k - k')t] \]  \hspace{1cm} (10.110)

or

\[ \partial_t \bar{E}(k,t) = -i \int_{-\infty}^{\infty} dk' \left( A(k',t) \bar{E}(k - k',t) \right. \]

\[ \times \exp \{ i[\omega(k) - \omega_s^s(k') - \omega(k - k')]t \} \]

\[ + B(k',t)\bar{E}(k - k',t) \exp \{ i[\omega(k) - \omega_s^s(k') - \omega(k - k')]t \} \]  \hspace{1cm} (10.111)
Induced Scattering

In the exponents on the right side of (10.111) we can already see the terms that will lead to the three-wave frequency matching conditions.

In order to put the "ion" equation (10.98) in the same form as the "electron" equation (10.111), it is useful to assume at this point that all of the terms with frequency exp \([-i\omega_s^+(k)t]\) will behave independently of all of the terms with frequency exp \([-i\omega_s^-(k)t]\). Then looking only for the terms on the left side of (10.98) with frequency exp \([-i\omega_s^+(k)t]\), we find

\[
(\partial_t^2 + k^2)A(k,t) \exp[-i\omega_s^+(k)t] = [\partial_t^2 A(k,t) - 2i\omega_s^+(k)\partial_t A(k,t)]
- [\omega_s^+(k)]^2 A(k,t) + k^2 A(k,t) \exp[-i\omega_s^+(k)t] \tag{10.112}
\]

The last two terms cancel by the definition (10.104) of \(\omega_s^+(k)\), and we ignore \(\partial_t^2 A\) compared to \(-2i\omega_s^+(k)\partial_t A\) just as in the derivation of the "electron" equation (10.88) in Section 7.16. We obtain for the entire equation (10.98)

\[
-2i\omega_s^+(k)\partial_t A(k,t) \exp[-i\omega_s^+(k)t]
= -k^2 \int_{-\infty}^{\infty} dk' \tilde{E}(k',t) \exp[-i\omega_l(k')t] \times \tilde{E}^*(k' - k,t) \exp[i\omega_l(k' - k)t] \tag{10.113}
\]

or

\[
\partial_t A(k,t) = \frac{-ik^2}{2\omega_s^+(k)} \int_{-\infty}^{\infty} dk' \tilde{E}(k',t)\tilde{E}^*(k' - k,t) \times \exp[i(\omega_s^+(k) - \omega_l(k') + \omega_l(k' - k))t] \tag{10.114}
\]

where the three-wave frequency matching conditions can again be seen popping up on the right side.

The equation for \(B(k,t)\) is obtained in the same manner, leading to the same equation as (10.114) with \(A\) replaced by \(B\) and \(\omega_s^+\) replaced by \(\omega_s^-\). This is

\[
\partial_t B(k,t) = \frac{-ik^2}{2\omega_s^-(k)} \int_{-\infty}^{\infty} dk' \tilde{E}(k',t)\tilde{E}^*(k' - k,t) \times \exp[i(\omega_s^-(k) - \omega_l(k') + \omega_l(k' - k))t] \tag{10.115}
\]

Equations (10.111), (10.114), and (10.115) are now a complete set of equations for the slowly varying amplitudes \(\tilde{E}, A,\) and \(B\).

In order to see clearly the method we are about to develop, let us consider the model equation

\[
\partial_t C(k,t) = \int_{-\infty}^{\infty} dk' V(k,k',k - k')C(k',t)C(k - k',t) \times \exp[i(\omega(k) - \omega(k') - \omega(k - k'))t] \tag{10.116}
\]

This model equation is easily seen to have the same basic structure of our three equations (10.111), (10.114), and (10.115).
The derivation proceeds formally with an expansion of the amplitude $C(k,t)$. To clearly distinguish the different terms in the expansion, we treat the "vertex" $V$ as the expansion parameter, even though it is really $C$ itself that is small in some sense.

Thus, we expand

$$C(k,t) = C^{(0)}(k,t) + C^{(1)}(k,t) + C^{(2)}(k,t) + \cdots$$  \hfill (10.117)

Substituting this in the basic dynamical equation (10.116) we obtain, to zeroth order in $V$,

$$\partial_t C^{(0)}(k,t) = 0$$  \hfill (10.118)

with solution

$$C^{(0)}(k,t) = C^{(0)}(k,t = 0)$$  \hfill (10.119)

which is just what linear physics would tell us; we choose this value to be $C(k,t = 0)$.

Next, the zeroth order solution (10.119) is substituted into the basic dynamical equation (10.116) to obtain

$$\partial_t C^{(1)}(k,t) = \int_{-\infty}^{\infty} dk' \, V(k,k',k - k')C^{(0)}(k')C^{(0)}(k - k')$$

$$\times \exp \{ i[\omega(k) - \omega(k') - \omega(k - k')]t \}$$  \hfill (10.120)

where we have dropped the time index on $C^{(0)}$ since it is a constant. The solution of (10.120) is

$$C^{(1)}(k,t) = \int_{0}^{t} dt' \int_{-\infty}^{\infty} dk' \, \exp \{ i[\omega(k) - \omega(k') - \omega(k - k')]t \}$$

$$\times V(k,k',k - k')C^{(0)}(k')C^{(0)}(k - k')$$  \hfill (10.121)

We can write this in a more symmetric form if we introduce

$$k'' \equiv k - k'$$  \hfill (10.122)

Then defining

$$F(k,k',k'',t) \equiv V(k,k',k'') \exp \{ i[\omega(k) - \omega(k') - \omega(k'')]t \}$$

$$\times \delta(k - k' - k'')$$  \hfill (10.123)

we can write (10.121) in the form

$$C^{(1)}(k,t) = \int_{-\infty}^{\infty} dk' \int_{-\infty}^{\infty} dk'' \, C^{(0)}(k')C^{(0)}(k'') \int_{0}^{t} dt' \, F(k,k',k'',t')$$  \hfill (10.124)

In this form, we should now consider $F$ as the expansion parameter.

The equation for $C^{(2)}$ is obtained by substituting $C = C^{(0)} + C^{(1)}$ on the right side of the basic dynamical equation (10.116) and picking out only those terms that are second order in $F$. We find
\[ \partial_t C^{(2)}(k, t) = \int_{-\infty}^{\infty} dk' \int_{-\infty}^{\infty} dk'' F(k, k', k'', t) \]
\[ \times [C^{(0)}(k')C^{(1)}(k'', t) + C^{(1)}(k', t)C^{(0)}(k'')] \]
\[ = \int_{-\infty}^{\infty} dk' \int_{-\infty}^{\infty} dk'' F(k, k', k'', t)[C^{(0)}(k') \int_{-\infty}^{\infty} dk''' \int_{-\infty}^{\infty} dk'''' \]
\[ \times C^{(0)}(k''')C^{(0)}(k''') \int_{0}^{t} dt' F(k'', k''', k''', t') \]
\[ + C^{(0)}(k'') \int_{-\infty}^{\infty} dk''' \int_{-\infty}^{\infty} dk'''' C^{(0)}(k''')C^{(0)}(k''') \]
\[ \times \int_{0}^{t} dt' F(k', k''', k''', t') ] \]
\[ (10.125) \]

which is integrated in time to yield
\[ C^{(2)}(k, t) = \int dk' dk'' dk''' dt' \int_{0}^{t} F(k, k', k'', t) F(k'', k''', k''', t'') \]
\[ \times \int_{0}^{t} dt' \int_{0}^{t} dt'' F(k, k', k'', t') F(k', k''', k''', t'') \]
\[ + \int dk' dk'' dk''' dt'' F(k, k', k'', t') F(k', k''', k''', t'') \]
\[ \times \int_{0}^{t} dt' \int_{0}^{t} dt'' F(k, k', k'', t') F(k', k''', k''', t'') \]
\[ (10.126) \]

This is the highest order term that we shall need for our theory.

At this point, we wish to introduce the idea of random phases. We want to develop a statistical theory of weak turbulence. One way to do this is to consider an ensemble of realizations, in each of which the absolute value of the amplitude \( C^{(0)} \), at a given wave number \( k \), is the same. However, the complex quantity
\[ C^{(0)}(k) \equiv |C^{(0)}(k)|e^{i\theta(k)} \]
\[ (10.127) \]

has a phase \( \theta(k) \), which is a random number \( 0 \leq \theta(k) < 2\pi \). Thus, \( |C^{(0)}(k)| \) is the same in each realization, but \( \theta(k) \) varies randomly from realization to realization.

Consider the two-point correlation function
\[ \langle C^{(0)}(k)C^{(0)}(k') \rangle = |C^{(0)}(k)| |C^{(0)}(k')| \langle e^{i\theta(k) + i\theta(k')} \rangle \]
\[ = |C^{(0)}(k)| |C^{(0)}(k')| \langle \cos [\theta(k) + \theta(k')] \rangle \]
\[ + i \sin [\theta(k) + \theta(k')] \]
\[ (10.128) \]

where \( \langle \cdot \rangle \) indicates ensemble average. If \( k \neq k' \), then \( \theta(k) \) and \( \theta(k') \) are statistically independent, which means (since any \( \theta \) between 0 and 2\( \pi \) is equally likely)
\[ \langle \cos[\theta(k) + \theta(k')] \rangle = \frac{\int_0^{2\pi} d\theta(k) \int_0^{2\pi} d\theta(k') \cos[\theta(k) + \theta(k')]}{\int_0^{2\pi} d\theta(k) \int_0^{2\pi} d\theta(k')} = 0 \quad (10.129) \]

The same thing happens for the \( \sin[\theta(k) + \theta(k')] \) term. If \( k = k' \), then
\[
\langle e^{i\theta(k) + i\theta(k')} \rangle = \langle e^{2i\theta(k)} \rangle = \langle \cos(2\theta(k)) + i\sin(2\theta(k)) \rangle = 0 \quad (10.130)
\]

Thus, we have for all \( k \) and \( k' \) that
\[
\langle C^{(0)}(k)C^{(0)}(k') \rangle = 0 \quad (10.131)
\]

However, consider
\[
\langle C^{(0)}(k)C^{(0)*}(k') \rangle = |C^{(0)}(k)|^2 \langle \langle e^{i\theta(k) - i\theta(k')} \rangle = \langle e^0 \rangle = \langle 1 \rangle = 1 \quad (10.132)
\]

When \( k = k' \) we have
\[
\langle e^{i\theta(k) - i\theta(k')} \rangle = \langle e^0 \rangle = \langle 1 \rangle = 1 \quad (10.133)
\]

whereas when \( k \neq k' \), Eq. (10.132) vanishes as before. Thus, the quantity in (10.132) is zero when \( k \neq k' \) and is nonzero when \( k = k' \); it must be a Dirac delta function. Thus, we write (10.132) as
\[
\langle C^{(0)}(k)C^{(0)*}(k') \rangle = n^{(0)}(k)\delta(k - k') \quad (10.134)
\]

where the quantity \( n(k) \) is sometimes called the mode occupation number by analogy to quantum theories of atomic transitions. In this section, we shall call \( n^{(0)}(k) \) the zeroth order intensity, since it is proportional to the square of the amplitude \( C^{(0)} \).

**[Note:** In this model problem, we have taken the phase \( \theta(k) \) to be statistically independent of the phase \( \theta(-k) \). In some cases, this assumption may need to be modified. For example, in the physics contained in the nonlinear Schrodinger equation, this assumption is quite appropriate for the amplitude \( E(k,t) \), but it is wrong for \( A(k) \) and \( B(k) \) as can be seen by (10.102) and (10.103). The result of treating these cases properly is to add more terms of the same form as we shall find for our model problem.]

The total intensity \( n(k,t) \) is related to the total amplitude \( C(k,t) = C^{(0)}(k,t) + C^{(1)}(k,t) + C^{(2)}(k,t) \) in the same way [Eq. (10.134)] that the zeroth order intensity \( n^{(0)} \) is related to the zeroth order amplitude \( C^{(0)} \):
\[
\langle C(k,t)C^*(k',t) \rangle = n(k,t)\delta(k - k') \quad (10.135)
\]

**EXERCISE** Show that the form (10.135) is a rigorous consequence of the assumption of statistical spatial homogeneity; that is, ensemble averages can only depend on spatial differences \( x - x' \), not on absolute spatial location, \( x \). See any introductory book on turbulence theory, for example, Leslie [10].
We look for an equation that describes the time evolution of $n(k,t)$. With the expansion (10.117) of the amplitude $C$, keeping only terms up to second order in $F$, we have (setting $k = k'$),

$$
|C(k,t)|^2 = |C^{(0)}|^2 + \langle C^{(0)}C^{(1)*} \rangle + \langle C^{(0)}C^{(2)*} \rangle + \langle C^{(0)}C^{(1)}C^{(1)*} \rangle + \langle C^{(0)}C^{(2)}C^{(2)*} \rangle + \langle C^{(1)}C^{(1)*} \rangle + \{\text{higher order terms}\}
$$

(10.136)

Many of the terms on the right of (10.136) vanish. For example, from (10.124) we see that all terms of the form $C^{(0)}C^{(1)*}$ look like

$$
\langle C^{(0)}C^{(1)*} \rangle \sim \langle C^{(0)}(k)C^{(0)*}(k')C^{(0)*}(k'') \rangle \\
\sim \langle e^{i\theta(k) - i\theta(k') - i\theta(k'')} \rangle \\
\sim 0
$$

(10.137)

**EXERCISE** Convince yourself of the last step.

Likewise, all terms of the form $C^{(0)}C^{(2)*}$ are of the form [see Eq. (10.126)]

$$
\langle C^{(0)}C^{(2)*} \rangle \sim \langle C^{(0)}(k)C^{(0)*}(k')C^{(0)*}(k'')(k''') \rangle \\
\sim \langle e^{i\theta(k) - i\theta(k') - i\theta(k'') - i\theta(k''')} \rangle \\
\sim 0
$$

(10.138)

**EXERCISE** Convince yourself of the last step.

[Note: When the conditions discussed in the previous note prevail, that is, $C(k)$ is correlated to $C(-k)$, then (10.137) still vanishes but (10.138) no longer vanishes in general.]

Thus, the only terms contributing in (10.136) are

$$
|\langle C(k,t) |^2 \rangle - |C^{(0)}(k)|^2 = |C^{(1)}(k,t)C^{(1)*}(k,t)|
$$

(10.139)

From (10.124), (10.134), and (10.135) we find

$$
\begin{align*}
[n(k,t) - n^{(0)}(k)]\delta(0) &= \int dk' dk'' dk''' \int_0^1 dt' F(k,k',k'',t') \\
&\cdot \int_0^1 dt'' F^*(k,k'',k''',t'') \\
&\cdot \langle C^{(0)}(k')C^{(0)}(k'')C^{(0)*}(k''')C^{(0)*}(k''') \rangle
\end{align*}
$$

(10.140)

where $\delta(0)$ means $\delta(k - k')|_{k = k'}$; in order for (10.140) to make any sense we will need to find a similar factor on the right side.

Consider the factor

$$
\langle C^{(0)}(k')C^{(0)}(k'')C^{(0)*}(k''')C^{(0)*}(k''') \rangle \sim \langle e^{i\theta(k') + i\theta(k'') - i\theta(k''') - i\theta(k''')} \rangle
$$

(10.141)
There are two possible ways to obtain a nonzero result on the right. The first is when
\[ k' = k'' \quad \text{and} \quad k'' = k''' \quad (10.142) \]
and the second is when
\[ k' = k''' \quad \text{and} \quad k'' = k''', \quad (10.143) \]
Thus,
\[ \langle C^{(0)}(k')C^{(0)}(k'')C^{(0)*}(k''')C^{(0)}(k''') \rangle 
- n^{(0)}(k')n^{(0)}(k'')\delta(k' - k'')\delta(k'' - k''') 
+ n^{(0)}(k')n^{(0)}(k'')\delta(k' - k''')\delta(k'' - k''') \quad (10.144) \]
Substituting this on the right of (10.140), and using the delta functions to perform the \( k'' \) and \( k''' \) integrations, we obtain
\[ [n(k,t) - n^{(0)}(k)]\delta(0) = \int dk' dk'' \int_0^t dt' \int_0^t dt'' 
\times F(k,k',k'',t')n^{(0)}(k')n^{(0)}(k'') 
\times \{ F*(k,k',k'',t'') + F*(k,k'',k',t''') \} \quad (10.145) \]
To make life simpler, let us assume for this model problem that
\[ V(k,k',k'') = V(k,k'',k') \quad (10.146) \]
which means that [see Eq. (10.123)]
\[ F(k,k',k'',t') = F(k,k'',k',t'') \quad (10.147) \]
Equation (10.145) then reads
\[
\begin{align*}
[n(k,t) - n^{(0)}(k)]\delta(0) = 2 & \int dk' dk'' n^{(0)}(k')n^{(0)}(k'') 
\times \left| \int_0^t dt' F(k,k',k'',t') \right| ^2 
\end{align*}
\quad (10.148) \]
From the definition (10.123),
\[ \left| \int_0^t dt' F \right|^2 \sim \left| \int_0^t dt' e^{i[\omega(k) - \omega(k')]t} \right|^2 \quad (10.149) \]
The idea of weak turbulence theory is to consider changes on a time scale long compared to that of any of the characteristic frequencies. With this in mind, we wish to apply to (10.149) the formula
\[ \lim_{t \rightarrow \infty} \left| \int_0^t dt' e^{i\Omega t} \right|^2 = 2\pi t \delta(\Omega) \quad (10.150) \]
Equation (10.150) can be derived as follows:
\[
\lim_{\epsilon \to 0} \left. \int_0^{t'} dt' e^{i\Omega t'} \right|_0^1 = \lim_{\epsilon \to 0} \left. \frac{1}{i\Omega} e^{i\Omega t'} \right|_0^1 = \lim_{\epsilon \to 0} \left. \frac{1}{i\Omega} (e^{i\Omega t'} - 1) \right|_0^1 = \lim_{\epsilon \to 0} \frac{1}{\Omega^2} (e^{i\Omega t/2} - e^{-i\Omega t/2})(e^{-i\Omega t/2} - e^{i\Omega t/2}) = \lim_{\epsilon \to 0} \frac{4}{\Omega^2} \sin^2 \left( \frac{\Omega t}{2} \right)
\]

(10.151)

Now, multiply the argument by \(t^{-1}\). Then, if \(\Omega \neq 0\), we have

\[
\lim_{t \to 0} \frac{4}{\Omega^2 t} \sin^2 \left( \frac{\Omega t}{2} \right) = 0
\]

(10.152)

If we first take the limit \(\Omega \to 0\), we obtain

\[
\lim_{\epsilon \to 0} \lim_{\Omega \to 0} \frac{4}{\Omega^2 t} \sin^2 \left( \frac{\Omega t}{2} \right) = \lim_{\epsilon \to 0} \frac{4}{\Omega^2 t} \left( \frac{\Omega t}{2} \right)^2 = \lim_{\epsilon \to 0} \frac{4}{\Omega^2 t} \left( \frac{\Omega t}{2} \right)^2 = \lim_{\epsilon \to 0} t = \infty
\]

(10.153)

Thus, the argument of (10.152) vanishes if \(\Omega \neq 0\), and becomes infinite if \(\Omega = 0\). Because it must therefore be proportional to \(\delta(\Omega)\), we write

\[
\lim_{\epsilon \to 0} \frac{4}{\Omega^2 t} \sin^2 \left( \frac{\Omega t}{2} \right) = \alpha \delta(\Omega)
\]

(10.154)

To determine the constant \(\alpha\), we integrate both sides over all \(\Omega\), to obtain

\[
\alpha = \int_{-\infty}^{\infty} d\Omega \lim_{\epsilon \to 0} \frac{4}{\Omega^2 t} \sin^2 \left( \frac{\Omega t}{2} \right) = 2 \int_{-\infty}^{\infty} \frac{dx}{x^2} \sin^2 x = 2\pi
\]

(10.155)

**Exercise** Obtain (10.155) by contour integration, moving the contour off of the nonexistent pole at \(x = 0\).
EXERCISE  By techniques similar to those used in the proof of (10.150), show that
\[
\lim_{t \to \infty} \int_0^t dt' e^{i\Omega t'} \int_0^t dt'' e^{-i\Omega t''} = \pi t \delta(\Omega)
\]
Finally, moving the factor $t$ to the right in (10.154), we obtain the result (10.150).
Using this result and the definition (10.123), we find
\[
\left| \int_0^t dt' F(k,k',k'',t') \right|^2 = |V(k,k',k'')|^2 2\pi t \delta[\omega(k) - \omega(k') - \omega(k'')] \times \delta(k - k' - k'') \delta(0)
\]
where one may write $\delta(x)\delta(x) = \delta(x)\delta(0)$ since $x = 0$ is the only value that counts. Substituting this into (10.148) and canceling a $\delta(0)$ on each side, we find
\[
n(k,t) - n^{00}(k) = 4\pi t \int dk' dk'' |V(k,k',k'')|^2 \times n^{00}(k') n^{00}(k'') \delta[\omega(k) - \omega(k') - \omega(k'')] \delta(k - k' - k'')
\]
This calculation started at $t = 0$ and went out a time $t$ that was considered long. However, considering the right side of (10.157) as tiny, we may say that only a small change in $n(k,t)$ results. Thus, one can imagine performing this calculation over and over again, each time inserting the new value of $n(k,t)$ on the right of (10.157) instead of $n^{00}(k)$. Dividing (10.157) by $t$, we obtain a differential equation for $n(k,t)$; the left side becomes
\[
\frac{n(k,t) - n^{00}(k)}{t} = \frac{\partial}{\partial t} n(k,t)
\]
Finally we have
\[
\frac{\partial}{\partial t} n(k,t) = 4\pi \int dk' dk'' |V(k,k',k'')|^2 n(k',t)n(k'',t) \times \delta[\omega(k) - \omega(k') - \omega(k'')] \delta(k - k' - k'')
\]
The important quantities on the right are the two delta functions, which indicate that wave number matching ($k = k' + k''$) and frequency matching ($\omega(k) = \omega(k') + \omega(k'')$) are operative.
Equation (10.159) is the basic result of weak turbulence theory as applied to fluid equations of the form (10.88) and (10.89). We will not present any of the details of these calculations, but rather we refer the reader to the extensive discussions in other places. (See Refs. [1] to [5], [11] to [16].) Let us conclude this section by describing qualitatively the predictions of the weak turbulence theory as applied to the equations (10.111), (10.114), and (10.115), which contain the nonlinear
Fig. 10.5 Behavior of the intensity $n_x(k,t)$ predicted by weak turbulence theory; $t_5 > t_4 > t_3 > t_0$.

coupling of Langmuir waves to ion-acoustic waves. For a large range of parameters, it is found (Fig. 10.5) that the intensity $n_x$, defined by $n_x(k,t)\delta(k-k') = \langle E(k,t)E^*(k,t) \rangle$, initially localized about some $k_0$, migrates to wave numbers localized about a wave number opposite in sign and somewhat smaller in magnitude than $k_0$. This process is the same as the parametric decay instability of Section 7.17. The process continues until the intensity piles up about $k = 0$. For some time this phenomenon of condensation in wave number space was thought of as a paradox in plasma physics, because Landau damping is small at small wave numbers so that in the absence of collisional damping, there was no known dissipation mechanism. We now know (Section 7.17) that intense waves localized around $k = 0$ can drive the oscillating two-stream instability leading to soliton formation. Since solitons are localized in configuration space, their formation leads to a broadening of $n_x(k,t)$ in wave number space and thus leads to the possibility of Landau damping. Unfortunately, the four-wave modulational instabilities cannot be treated within the context of the weak turbulence theory of the present chapter. The development of a complete theory of Langmuir turbulence including modulational instability and soliton formation is only one of the many fascinating aspects of nonlinearity and turbulence that are being treated in current research in plasma physics ([6], [16] to [31]).

Weak Turbulence Theory

PROBLEM

10.1 Quasilinear Theory

(a) Suppose two electron beams are incident on a Maxwellian plasma, so that the one-dimensional distribution function is as shown in Fig. 10.6. Using the ideas of quasilinear theory, consider an initial value problem consisting of
the distribution as shown plus a small noise level of electric field fluctuations. Draw a series of sketches, at several different times, of: the growth rate of Langmuir waves as a function of wave number; the intensity of Langmuir waves as a function of phase speed; and the distribution function. Use \( u_1, u_2, u_3, \) and \( u_4 \) as benchmarks. Make your final set of sketches correspond to \( t \to \infty \). Crudely estimate a time scale for this entire process, using the electron plasma frequency and the ratio \( n_e/n_0 \) where \( n_0 \) is the density of beam particles.

(b) The derivation of quasilinear theory proceeded from the Vlasov equation and thus left out certain physics. Discuss this physics, and recall an equation from an earlier chapter that would allow us to include this physics. Draw a new set of sketches as in part (a), using the \( t \to \infty \) sketch of part (a) as the \( t = 0 \) sketch of part (b). Make your final set of sketches correspond to \( t \to \infty \). Crudely estimate a time scale for this entire process.

In each of parts (a) and (b), state explicitly what is being assumed about the ions. Should this be the same in each part?
Appendix A

Derivation of the Lenard–Balescu Equation

In this appendix, we complete the derivation of the Lenard–Balescu equation (5.19) starting from Eqs. (5.1) and (5.4), which in turn are obtained from the BBGKY hierarchy by discarding three-particle correlations (Refs. [1] to [5]). From (5.1) and (5.4) to (5.8), we have

\[ \partial_t f_i(v_i, t) = - n_0 \int dx_2 \, dv_2 a_{12} \cdot \nabla_{v_i} g(x_1 - x_2, v_1, v_2, t) \]  
\[ \frac{\partial}{\partial t} g(x_1 - x_2, v_1, v_2, \tau) + V_1 g + V_2 g = S(x_1 - x_2, v_1, v_2) \]  
\[ V_1 g(12) = v_1 \cdot \nabla_{x_i} g(12) \]  
\[ + [n_0 \int d3 \, a_{13} g(32)] \cdot \nabla_{v_i} f_i(v_i) \]  
\[ V_2 g(12) = v_2 \cdot \nabla_{x_i} g(12) \]  
\[ + [n_0 \int d3 \, a_{23} g(13)] \cdot \nabla_{v_i} f_i(v_2) \]  
\[ S(x_1 - x_2, v_1, v_2) = - (a_{12} \cdot \nabla_{v_i} + a_{21} \cdot \nabla_{v_j}) f_i(v_i) f_j(v_j) \]

where we have used \( g(32) = g(23) \), we alternate between the notations (1) and (x_1, v_1) depending on convenience, and we recall from Chapter 5 that we wish to solve for \( g(\tau \to \infty) \) where \( \tau \) is the fast time scale on which \( g \) relaxes. On this fast time scale, the functions \( f_i \) and thus \( S \) are considered to be constants. We shall also need, from (5.9),

\[ a_{ij} = \frac{e^2}{m_e |x_i - x_j|^3} (x_i - x_j) \]
Using the Fourier transform conventions in Chapter 5, we spatially Fourier transform these equations with respect to $x_1$ and $x_2$. Because of the appearance of the combination $(x_1 - x_2)$, we obtain the factor $\delta(k_1 + k_2)$ in several places and, thus, can replace $k_2$ by $-k_1$.

**EXERCISE** For any function $f(x_1 - x_2)$, show that the double Fourier transform with respect to $x_1$ and $x_2$ is $\delta(k_1 + k_2) f(k_1)$ where $f(k)$ is the Fourier transform of $f(x)$ with respect to $x$.

**EXERCISE** Show that $\int dx f_1(x)f_2(x) = (2\pi)^3 \int dk f_1(-k)f_2(k)$ for any functions $f_1$ and $f_2$; here, $f_i(k)$ is the Fourier transform of $f_i(x)$, etc., as usual.

**EXERCISE** Show that the double Fourier transform of $\int dx_3 f_1(x_1 - x_3) \times f_2(x_2 - x_3)$ is $(2\pi)^3 \delta(k_1 + k_2)f_1(k_1)f_2(-k_1)$.

With the results of these exercises, and Eq. (5.16) for $a_{12}$, the Fourier transformed version of (A.1) to (A.6) is

$$\partial_t f_1(v_1,t) = -\frac{in_0(2\pi)^3}{m_e} \nabla v_i \cdot \int dv_i dk_i \phi(k_i)g(k_i, v_1, v_2, \tau) = \infty \quad (A.7)$$

$$\frac{\partial}{\partial t} g(k_1, v_1, v_2, \tau) + V_1g + V_2g = S(k_1, v_1, v_2) \quad (A.8)$$

$$V_1g(12) = i k_1 \cdot v_1 g(12)$$

$$- \frac{n_0(2\pi)^3}{m_e} i k_1 \cdot \nabla v_i f_1(v_i) \phi(k_1) \int dv_3 g(k_1, v_1, v_3, \tau) \quad (A.9)$$

$$V_2g(12) = -i k_1 \cdot v_2 g(12)$$

$$+ \frac{n_0(2\pi)^3}{m_e} i k_1 \cdot \nabla v_i f_1(v_i) \phi(k_1) \int dv_3 g(k_1, v_1, v_3, \tau) \quad (A.10)$$

$$S(k_1, v_1, v_2) = \frac{\phi(k_1)}{m_e} i k_1 \cdot (\nabla v_i - \nabla v_j) f_1(v_i) f_1(v_2) \quad (A.11)$$

Our goal is to express the right side of (A.7) in terms of $f_i$ by solving (A.8) for $g$. With (A.7) in its present form, the remainder of the calculation can be performed in wave number space; because of the factor $i$ on the right of (A.7) and the fact that the right of (A.7) must be real, we need only calculate the imaginary part of $g(k_1, v_1, v_2, \tau) = \infty$.

The solution of (A.8) for $g(k_1, v_1, v_2, \tau) = \infty$ is accomplished by Laplace transforming with respect to the fast time $\tau$.

**EXERCISE** For any function $g(t)$, show that the Laplace transform of $dg/dt$ is $-g(t = 0) - i \omega g(\omega)$. 
With the result of this exercise, the Laplace transform of (A.8) is

\[ -g(k_1, v_1, v_2, \tilde{t} = 0) - i\omega g(k_1, v_1, v_2, \omega) + V_1 g(12\omega) + V_2 g(12\omega) = -\frac{1}{i\omega} S(k_1, v_1, v_2) \]  

(A.12)

where \( g(\omega) \) is defined only for \( \omega_i \equiv \text{Im}(\omega) \) sufficiently large, and where the operators \( V_1 \) and \( V_2 \) can be regarded as numbers since they have no time dependence in (A.9) and (A.10). Solving (A.12) for \( g(\omega) \) we find

\[ g(\omega) = \frac{g(\tilde{t} = 0) - (S/i\omega)}{-i\omega + V_1 + V_2} \]  

(A.13)

We require \( g(\tilde{t} = \infty) \). This can be obtained from the inverse Laplace transform of (A.13). It turns out that distribution functions \( f_i(v) \) that are stable in the Vlasov sense (Chapter 6) are such that the zeros of \( -i\omega + V_1 + V_2 \) always occur in the lower half \( \omega \)-plane. We consider only such stable distribution functions \( f_i(v) \). Thus, the inverse Laplace transform

\[ g(\tilde{t}) = \int L \frac{d\omega}{2\pi} \frac{g(\tilde{t} = 0) - S/i\omega}{-i\omega + V_1 + V_2} e^{-i\omega t} \]  

(A.14)

can be performed by deforming the Laplace contour as shown in Fig. A.1. Since poles in the lower half plane contribute only damped functions of time, \( \sim \exp(\omega t) \), the only pole that contributes to \( g(\tilde{t} = \infty) \) is the one at \( \omega = 0 \); therefore,

\[ g(\tilde{t} = \infty) = \lim_{\omega \to 0} \frac{S}{-i\omega + V_1 + V_2} \]  

(A.15)

Fig. A.1  Inverse Laplace contour for calculating \( g(\tilde{t} = \infty) \).
where we retain the $\lim_{\omega \to 0}$ to help us interpret other contour integrations that occur in the calculation.

At this point, we introduce a trick that allows us to treat the operators $V_1$ and $V_2$ separately, rather than in the combination $V_1 + V_2$. Consider

$$\frac{1}{-i\omega + V_1 + V_2} = \int_0^\infty dt \ e^{i(\omega - V_1 - V_2)t}$$

$$= \int_0^\infty dt \ e^{i\omega t} \int_{C_1} \frac{d\omega_1}{2\pi} \ e^{-i\omega t} \int_{C_2} \frac{d\omega_2}{2\pi} \ e^{-i\omega_2 t}$$

$$= \int_{C_1} \frac{d\omega_1}{2\pi} \int_{C_2} \frac{d\omega_2}{2\pi} \frac{1}{-i\omega_1 + V_1} \frac{1}{-i\omega_2 + V_2} \frac{1}{-i(\omega - \omega_1 - \omega_2)}$$

(A.16)

where the contours $C_1$ and $C_2$ must be chosen so that $\omega_i > \omega_{1i} + \omega_{2i}$. Then (A.15) becomes

$$g(k_1, v_1, v_2, \alpha, \eta) = \infty$$

$$= \lim_{\omega \to 0} \ \int_{C_1} \frac{d\omega_1}{2\pi} \int_{C_2} \frac{d\omega_2}{2\pi} \frac{1}{-i\omega_1 + V_1} \frac{1}{-i\omega_2 + V_2} \frac{1}{-i(\omega - \omega_1 - \omega_2)} \frac{S(k_1, v_1, v_2)}{i(\omega - \omega_1 - \omega_2)}$$

(A.17)

In expressions (A.13) to (A.17), we interpret the meaning of an inverse operator $(-i\omega_1 + V_1)^{-1}F$ acting on a function $F$ to be that function $G$ such that $F = (-i\omega_1 + V_1)G$.

We first need

$$\alpha(k_1, v_1, v_2) = \frac{1}{-i\omega_1 + V_1} S(k_1, v_1, v_2)$$

(A.18)

such that

$$S(k_1, v_1, v_2) = (-i\omega_1 + V_1)\alpha(k_1, v_1, v_2)$$

$$= (-i\omega_1 + ik_1 \cdot v_1)\alpha(k_1, v_1, v_2) - \frac{i(2\pi)^3 n_0}{m_e} k_1 \cdot \nabla v_1$$

$$\times f_1(v_1) \phi(k_1) \int dv_2 \ \alpha(k_1, v_2, v_3)$$

(A.19)

In order to solve this for $\alpha$ we must first eliminate $\int dv_3 \ \alpha$; we express (A.19) as

$$\alpha(k_1, v_1, v_2) = \frac{1}{-i\omega_1 + ik_1 \cdot v_1} [S(k_1, v_1, v_2)$$

$$+ \frac{i(2\pi)^3 n_0}{m_e} k_1 \cdot \nabla v_1 f_1(v_1) \phi(k_1) \int dv_3 \ \alpha(k_1, v_3, v_2)]$$

(A.20)

and integrate over all $v_1$ to find
\[ \int dv_1 \alpha(k_1, v_1, v_2) \]
\[ = \int dv_1 \frac{S(k_1, v_1, v_2)}{-i\omega_1 + ik_1 \cdot v_1} + \left[ \int dv_3 \alpha(k_1, v_3, v_2) \right] \times \frac{i(2\pi)^3 n_0}{m_e} \varphi(k_1) \int dv_1 \frac{k_1 \cdot \nabla v_1 f_1(v_1)}{-i\omega_1 + ik_1 \cdot v_1} \]  
(A.21)

Realizing that \( v_3 \) on the right is merely a dummy variable of integration, we find
\[ \int dv_3 \alpha(k_1, v_3, v_2) = \frac{1}{\epsilon(k_1, \omega_1)} \int dv_3 \frac{S(k_1, v_3, v_2)}{-i\omega_1 + ik_1 \cdot v_3} \]  
(A.22)

where
\[ \epsilon(k_1, \omega_1) = 1 + \frac{\omega_1^2}{k_1^2} \int dv_1 \frac{k_1 \cdot \nabla v_1 f_1(v_1)}{\omega_1 - k_1 \cdot v_1} \]  
(A.23)

is the dielectric function encountered in Chapter 6. Thus, (A.20) becomes
\[ \alpha(k_1, v_1, v_2) = \frac{1}{-i\omega_1 + ik_1 \cdot v_1} \left[ S(k_1, v_1, v_2) \right. \]
\[ \left. + \frac{i(2\pi)^3 n_0 k_1 \cdot \nabla v_1 f_1(v_1) \varphi(k_1)/m_e}{\epsilon(k_1, \omega_1)} \int dv_1 \frac{S(k_1, v_3, v_2)}{-i\omega_1 + ik_1 \cdot v_3} \right] \]  
(A.24)

which completes the inversion of the operator \((-i\omega_1 + V_1)^{-1}\).

Next, we need
\[ \int dv_2 \beta(k_1, v_1, v_2) = \int dv_2 \frac{1}{-i\omega_2 + V_2} \alpha(k_1, v_1, v_2) \]  
(A.25)

where we have noted from (A.7) that we need \( \int dv_2 g \) rather than \( g \), allowing us to use the compact analogue of (A.22). Noting that \( V_2 \) is the same as \( V_1 \) if the sign of \( k_1 \) is changed and if \( v_1 \) and \( v_2 \) are interchanged appropriately, we find
\[ \int dv_2 \beta(k_1, v_1, v_2) = \frac{1}{\epsilon(-k_1, \omega_2)} \int dv_2 \frac{\alpha(k_1, v_1, v_2)}{-i\omega_2 - ik_1 \cdot v_2} \]  
(A.26)

With the result (A.26) we have from (A.17)
\[ \int dv_2 g(k_1, v_1, v_2, \tau = \infty) \]
\[ = \lim_{\omega \to 0} \int_{C_1} \frac{d\omega_1}{2\pi} \int_{C_2} \frac{d\omega_2}{2\pi} \frac{1}{\epsilon(-k_1, \omega_2)} \frac{1}{-i(\omega - \omega_1 - \omega_2)} \]
\[ \times \int dv_2 \frac{1}{-i\omega_2 - ik_1 \cdot v_2} \frac{1}{-i\omega_1 + V_1} S(k_1, v_1, v_2) \]  
(A.27)

We perform the \( \omega_2 \) integration first, along the contour \( C_2 \) shown in Fig. (A.2). Since the integrand behaves like \( \omega_2^{-2} \) for large \( \omega_2 \), we can close the contour upward
Fig. A.2 Contour $C_2$ used in evaluating (A.27).

and pick up only the pole at $\omega_2 = \omega - \omega_1$, yielding

$$
\int dv_2 g(k_1,v_1,v_2,\tilde{t}) = \infty = \lim_{\omega \to 0} \int dv_2 \int_{C_1} \frac{d\omega_1}{2\pi} \times \frac{1}{\epsilon(-k_1,\omega - \omega_1)} \frac{1}{-i(\omega - \omega_1) - i k_1 \cdot v_2} \frac{1}{-i\omega_1 + V_1} S(k_1,v_1,v_2)
$$

(A.28)

Inserting the results (A.11) and (A.24) we have

$$
\int dv_2 g(k_1,v_1,v_2,\tilde{t}) = \infty = \lim_{\omega \to 0} \int dv_2 \int_{C_1} \frac{d\omega_1}{2\pi} \times \frac{1}{\epsilon(-k_1,\omega - \omega_1)} \frac{1}{-i(\omega - \omega_1) - i k_1 \cdot v_2} \frac{1}{-i\omega_1 + i k_1 \cdot v_1}

\times \left[ \frac{i k_1}{m_v} \cdot \varphi(k_1)(\nabla_{v_1} - \nabla_{v_2}) f_1(v_1) f_1(v_2) \right.

- \frac{i(2\pi)^n n_0 k_1 \cdot \nabla_v f_1(v_1) \varphi^2(k_1)/m_v}{\epsilon(k_1,\omega_1)}

\left. \times \int dv_3 \frac{k_1 \cdot (\nabla_{v_1} - \nabla_{v_3})}{\omega_1 - k_1 \cdot v_3} f_1(v_3) f_1(v_2) \right] \quad (A.29)
$$

There are four numbered terms in the square brackets. Including the $v_2$ integration and the denominator containing $v_3$, we have
\[ \frac{-i\mathbf{k}_1 \cdot \varphi(k_1)}{m_e} f_i(v_1) \int dv_2 \frac{\nabla_v f_i(v_2)}{-i(\omega - \omega_1) - i\mathbf{k}_1 \cdot v_2} \]

\[ = \frac{-f_i(v_1)}{n_0(2\pi)^3} [\epsilon(-\mathbf{k}_1, \omega - \omega_1) - 1] \quad (A.30) \]

where (A.23) has been used. Similarly,

\[ \frac{-i(2\pi)^3 n_0}{\epsilon(k_1, \omega_1)} \left[ \int dv_2 \frac{-f_i(v_2)}{-i(\omega - \omega_1) - i\mathbf{k}_1 \cdot v_2} \right] \]

\[ \times \mathbf{k}_1 \cdot \nabla_v f_i(v_1) \varphi(k_1)/m_e \left[ \frac{\varphi(k_1)}{m_e} \int dv_3 \frac{k_1 \cdot \nabla_v f_i(v_3)}{\omega_1 - k_1 \cdot v_3} \right] \]

\[ = \left[ 1 - \frac{1}{\epsilon(k_1, \omega_1)} \right] \frac{(-i)\mathbf{k}_1 \cdot \nabla_v f_i(v_1)}{m_e} \frac{\varphi(k_1)}{m_e} \]

\[ \times \int dv_2 \frac{f_i(v_2)}{-i(\omega - \omega_1) - i\mathbf{k}_1 \cdot v_2} \quad (A.31) \]

where (A.23) has been used again. Likewise,

\[ \frac{i\mathbf{k}_1 \cdot \varphi(k_1)}{m_e} (2\pi)^3 n_0 \int dv_2 \frac{\nabla_v f_i(v_2)}{-i(\omega - \omega_1) - i\mathbf{k}_1 \cdot v_2} \]

\[ \times \frac{\mathbf{k}_1 \cdot \nabla_v f_i(v_1) \varphi(k_1)/m_e}{\epsilon(k_1, \omega_1)} \int dv_3 \frac{f_i(v_3)}{\omega_1 - k_1 \cdot v_3} \]

\[ = \left[ \frac{\epsilon(-\mathbf{k}_1, \omega - \omega_1) - 1}{\epsilon(k_1, \omega_1)} \right] \frac{\mathbf{k}_1 \cdot \nabla_v f_i(v_1) \varphi(k_1)}{m_e} \]

\[ \times \int dv_3 \frac{f_i(v_3)}{\omega_1 - k_1 \cdot v_3} \quad (A.32) \]

Cancelling term \( \Theta \) with one of the terms in term \( \Theta \), we combine the remaining terms to obtain

\[ \int dv_3 g(k_1, v_1, v_2, \tilde{t} = \infty) = \lim_{\omega_1 \to 0} \int_{c_1} \frac{d\omega_1}{2\pi} \frac{1}{-i\omega_1 + i\mathbf{k}_1 \cdot v_1} \]

\[ \times \left\{ \left[ 1 - \frac{1}{\epsilon(-\mathbf{k}_1, \omega - \omega_1)} \right] - \frac{f_i(v_1)}{n_0(2\pi)^3} + \frac{\mathbf{k}_1 \cdot \nabla_v f_i(v_1) \varphi(k_1)/m_e}{\epsilon(k_1, \omega_1)} \right\} \]

\[ \times \left\{ \frac{f_i(v_2)}{\omega_1 - k_1 \cdot v_2} + \frac{\mathbf{k}_1 \cdot \nabla_v f_i(v_1) \varphi(k_1)/m_e}{\epsilon(k_1, \omega_1)\epsilon(-\mathbf{k}_1, \omega - \omega_1)} \right\} \]

\[ \times \int dv_2 \frac{f_i(v_2)}{-i(\omega - \omega_1) - i\mathbf{k}_1 \cdot v_2} \quad (A.33) \]
where a change of dummy variable has occurred in term (2). Recalling from below (A.16) that we still have \( \omega_i > \omega_i \) along the \( C_1 \) contour, and recalling that stable distributions \( f_s(v) \) imply that the zeroes of \( \epsilon(k, \omega) \) occur only for \( \omega_i < 0 \), the \( C_1 \) contour and the poles of the integrand on the right of (A.33) are as shown in Fig. A.3. Note that not all of the poles occur for each of the terms in (A.33).

Term (2) is evaluated by closing the contour \( C_1 \) downward, yielding a contribution only from the pole at \( \omega_1 = k_1 \cdot v_1 \), which gives

\[
\mathcal{O} = -\frac{f_s(v_1)}{n_0(2\pi)^3} \left[ 1 - \frac{1}{\epsilon(-k_1, \omega - k_1 \cdot v_1)} \right] \quad (A.34)
\]

**EXERCISE** Convince yourself that the integrand falls off fast enough at large \( \omega_1 \) to allow the contour to be closed downward.

Term (2) \( \times \mathcal{O} \) vanishes when the contour is closed upward. Finally, we consider the remaining two pieces together; these are

\[
\mathcal{O} \times \mathcal{O} + \mathcal{O} = \lim_{w \to 0} \int_{C_1} \frac{d\omega_1}{2\pi} \frac{1}{-i\omega_1 + ik_1 \cdot v_1} \frac{1}{\epsilon(-k_1, \omega - \omega_1)}
\]

\[
\times \frac{1}{\epsilon(k_1, \omega_1)} \frac{1}{k_1 \cdot v_1} \cdot f_s(v_1) \frac{\omega(k_1)}{m_e} \int dv_2 f_s(v_2)
\]

\[
\times \left[ \frac{-1}{\omega_1 - k_1 \cdot v_2} + \frac{1}{\omega_1 - \omega - k_1 \cdot v_2} \right] \quad (A.35)
\]

At this point it is convenient to use the fact that in (A.7) we only need the imaginary part of \( \int dv_2 g \). As we move the contour in Fig. A.3 down to the real axis (let \( \omega \to 0 \)), the integrand of (A.35) appears to vanish. However, we must be careful at the pole \( \omega_1 = k_1 \cdot v_1 \) and at the two poles that pinch the contour at \( \omega_1 = k_1 \cdot v_2 \) and \( \omega_1 = \omega + k_1 \cdot v_2 \). Recall the Plemelj formulas,
\[
\lim_{\eta \to 0} \frac{1}{\omega - a \pm i\eta} = P \left( \frac{1}{\omega - a} \right) \mp i\pi\delta(\omega - a) \tag{A.36}
\]

where the upper sign is used when a contour passes above a pole, and the lower sign is used when a contour passes below a pole. Then

\[
\Re \lim_{\omega \to 0} \frac{1}{\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_1} \left[ \frac{-1}{\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_2} + \frac{1}{\omega_1 - \omega - \mathbf{k}_1 \cdot \mathbf{v}_2} \right] = \Re \left[ P \left( \frac{1}{\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_1} \right) \mp i\pi\delta(\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_1) \right] \times \left[ - P \left( \frac{1}{\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_2} \right) + i\pi\delta(\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_2) \right] + P \left( \frac{1}{\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_2} \right) + i\pi\delta(\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_2) = 2\pi^2\delta(\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_1)\delta(\omega_1 - \mathbf{k}_1 \cdot \mathbf{v}_2) \tag{A.37}
\]

where \(\Re\) indicates the real part. If we use one of the \(\delta\)-functions to perform the \(\omega_1\) integration, (A.35) yields

\[
\text{Im}[\mathcal{O} \times \mathcal{O} + \mathcal{O}] = i\pi\mathbf{k}_1 \cdot \nabla_{\mathbf{v}_1} f_1(\mathbf{v}_1) \frac{\varphi(k_1)}{m_e} \times \int d\mathbf{v}_2 \frac{\delta[\mathbf{k}_1 \cdot (\mathbf{v}_1 - \mathbf{v}_2)] f_1(\mathbf{v}_2)}{|e(\mathbf{k}_1, \mathbf{k}_1 \cdot \mathbf{v}_1)|^2} \tag{A.38}
\]

where we have used the fact that \(e(-\mathbf{k}, -\omega) = e^*(\mathbf{k}, \omega)\) when \(\omega\) is real.

**EXERCISE** Demonstrate this fact from the definition (A.23) of \(e(\mathbf{k}, \omega)\). Show that for \(\omega\) real, \(\text{Im}[e(\mathbf{k}, \omega)] = -i\pi(\omega^2/k^2) \int d\mathbf{v} [(\mathbf{k} \cdot \nabla_{\mathbf{v}} f_1(\mathbf{v})) \delta(\omega - \mathbf{k} \cdot \mathbf{v})].\)

Similarly, if one uses the results of the exercise,

\[
\text{Im}[\mathcal{O}] = \frac{f_1(\mathbf{v}_1)}{n_0(2\pi)^3} \frac{\text{Im}[e(\mathbf{k}_1, \mathbf{k}_1 \cdot \mathbf{v}_1)]}{|e(\mathbf{k}_1, \mathbf{k}_1 \cdot \mathbf{v}_1)|^2} = \frac{-i\pi f_1(\mathbf{v}_1)\varphi(k_1)/m_e}{|e(\mathbf{k}_1, \mathbf{k}_1 \cdot \mathbf{v}_1)|^2} \times \int d\mathbf{v}_2 [\mathbf{k}_1 \cdot \nabla_{\mathbf{v}_1} f_1(\mathbf{v}_2)] \delta[\mathbf{k}_1 \cdot (\mathbf{v}_1 - \mathbf{v}_2)] \tag{A.39}
\]

Finally, inserting (A.38) and (A.39) into (A.7), one obtains

\[
\partial_t f_1(\mathbf{v}_1, t) = -\frac{8\pi^4 n_0}{m_e^2} \nabla_{\mathbf{v}_1} \cdot \int d\mathbf{k}_1 d\mathbf{v}_2 \frac{\mathbf{k}_1 \mathbf{k}_1 \cdot \omega^2(k_1)}{|e(\mathbf{k}_1, \mathbf{k}_1 \cdot \mathbf{v}_1)|^2} \times \delta[\mathbf{k}_1 \cdot (\mathbf{v}_1 - \mathbf{v}_2)][f_1(\mathbf{v}_1)\nabla_{\mathbf{v}_1} f_1(\mathbf{v}_2) - f_1(\mathbf{v}_2)\nabla_{\mathbf{v}_1} f_1(\mathbf{v}_1)] \tag{A.40}
\]

which with appropriate changes of variables is the Lenard–Balescu equation (5.19).
REFERENCES

B.1 Langevin Equation and Fluctuation-Dissipation Theorem

The discussion of plasma kinetic theory, including collisions, in Chapters 3, 4, and 5, led to the Fokker–Planck form of the plasma kinetic equation in (5.31). This is not a coincidence. In this appendix, it is shown that the Fokker–Planck equation arises naturally whenever a probability distribution [i.e., the one particle distribution function \( f_1(v,t) \)] changes slowly in time because of huge numbers of small changes (i.e., small angle collisions).

In order to motivate the Fokker–Planck equation, we use a physical example that is simpler than a plasma; namely, the case of Brownian motion. This will lead us to the related topics of the Langevin equation, the fluctuation-dissipation theorem, and Markov processes. As we study the example of Brownian motion, ask yourself how each step corresponds to its analogue in the plasma case.

The Langevin equation arises whenever a variable experiences a slow time variation as a result of a rapidly varying force. The best known example of this is the case of Brownian motion. A large particle (mass \( \sim 10^{-12} \) gram) exhibits Brownian motion when bombarded by the molecules in air (mass \( \sim 10^{-22} \) gram). The path of the particle may look as shown in Fig. B.1. The human eye, looking through a microscope, cannot see the fine structure on the curve shown, and so instead [1, 2] sees the curve in Fig. B.2. The wandering motion is, essentially, a random walk due to the large number of collisions that the particle suffers per unit time with the gas molecules. Picking out one of the dimensions of the motion, we can write Newton’s force law in one spatial dimension,

\[
\frac{dv(t)}{dt} = F(t)
\]  
(B.1)
where $F(t)$ is the force per unit mass on the Brownian particle. Thus, $F(t)$ contains the sum of many collisions, each lasting an extremely short time.

To study the physics of (B.1), we can consider an ensemble of realizations, each having the same initial speed $v(t = 0) = v_0$ but different random functions $F(t)$. Our intuition tells us that the overall effect of the many collisions will be to slow the Brownian particle, so that $\langle v(t) \rangle = 0$ as $t \to \infty$.

Microscopically, the Brownian particle slows because it collides with more particles in the direction of motion than in the opposite direction. It thus gives up net kinetic energy to the gas molecules, which leave the collision with a net gain in right-going momentum.

This discussion leads to the conclusion that the ensemble average of the force on the right of (B.1) must contain a term that tends to slow the Brownian particle.
Thus, we split the force $F(t)$ into two terms,
\[ F(t) = \langle F(t) \rangle + \delta F(t) \]  
(B.2)
so that $\langle \delta F(t) \rangle = 0$. The ensemble averaged part of $F(t)$ will depend on the properties of the gas, and on the speed $v$ of the Brownian particle. Suppose we Taylor expand this quantity in terms of the particle speed $v$:
\[ \langle F(t) \rangle = c_1 + c_2 v + c_3 v^2 + \ldots \]  
(B.3)
When $v = 0$, we want $\langle F \rangle = 0$, since there is then no preferred direction; thus, $c_1 = 0$. Let us then keep only the next term in (B.3). Because we expect this term to slow the particle, we introduce the minus sign explicitly through the introduction of a new constant $\nu$ such that $c_2 = -\nu$; our force equation (B.1) now reads
\[ \frac{d\nu(t)}{dt} = -\nu \nu(t) + \delta F(t) \]  
(B.4)
which is the famous \textit{Langevin equation} (Refs. [3] to [7]).
The constant $\nu$ in (B.4) represents dissipation. This can be seen by taking the ensemble average of (B.4)
\[ \frac{d}{dt} \langle \nu(t) \rangle = -\nu \langle \nu(t) \rangle \]  
(B.5)
so that
\[ \langle \nu(t) \rangle = v_0 e^{-\nu t} \]  
(B.6)
(Recall that each realization of the ensemble has initial speed $v_0$). Thus, the characteristic slowing down time is $\nu^{-1}$, and since the slowing down means a decrease in kinetic energy, $\nu$ represents dissipation.
Let us next investigate some of the statistical properties of (B.4). This equation is a linear inhomogeneous first order ordinary differential equation and thus is easy to solve. We have
\[ \frac{d\nu(t)}{dt} + \nu \nu = \delta F(t) \]  
(B.7)
Multiplying each side by $e^{\nu t}$ we have
\[ \frac{d}{dt} \left[ \nu(t) e^{\nu t} \right] = e^{\nu t} \delta F(t) \]  
(B.8)
Thus
\[ \nu(t) e^{\nu t} = v_0 + \int_0^t dt' \delta F(t') e^{\nu t'} \]  
(B.9)
or
\[ \nu(t) = v_0 e^{-\nu t} + e^{-\nu t} \int_0^t dt' \delta F(t') e^{\nu t'} \]  
(B.10)
The ensemble average of this equation reproduces (B.6),
\[ \langle \nu(t) \rangle = v_0 e^{-\nu t} \]  
(B.6)
Next, we square the velocity and ensemble average. Using (B.10), we have

\begin{align*}
\langle \nu^2(t) \rangle &= \langle [v_0 e^{-\nu t} + e^{-\nu t} \int_0^t dt' \delta F(t') e^{\nu t'}] \\
&\quad \times [v_0 e^{-\nu t} + e^{-\nu t} \int_0^t dt'' \delta F(t'') e^{\nu t''}] \rangle \\
&= v_0^2 e^{-2\nu t} + e^{-2\nu t} \int_0^t dt' e^{\nu t'} \int_0^t dt'' \langle \delta F(t') \delta F(t'') \rangle e^{\nu t''}
\end{align*}

(B.11)

where two terms have disappeared in the ensemble average.

We now make the important assumption that $\delta F$ is only correlated with itself over a time $\tau$, extremely short compared to the characteristic dissipation time $\nu^{-1}$ (Fig. B.3). We furthermore assume that $\delta F$ is a stationary process, so that $\langle \delta F(t') \delta F(t'') \rangle$ is only a function of the time difference $t' - t''$. The correlation time $\tau$ is roughly the time of one molecular collision.

We are interested in the integral

\[ I \equiv e^{-2\nu t} \int_0^t dt' e^{\nu t'} \int_0^t dt'' \langle \delta F(t') \delta F(t'') \rangle e^{\nu t''} \quad \text{(B.12)} \]

The above arguments indicate that the integrand is only important (nonzero) for $t' \approx t''$, as shown in Fig. B.4. With the change of variable $y = t' - t''$, $dy =$

![Diagram](image)

**Fig. B.4** Region of the $t'-t''$ plane that contains a substantial contribution to the integral in (B.12).
Fig. B.5 Region of the $t'$-$y$ plane that contains a substantial contribution to the integral in (B.13).

\[-d' t'', \text{ (B.12) becomes} \]

\[
I = e^{-2\nu t} \int_0^t dt' e^{2\nu t'} \int_{t'-t}^{t'} dy \ e^{\nu t'-\nu y} \langle \delta F(t') \delta F(t' - y) \rangle \tag{B.13}
\]

By stationarity, we can write

\[
\langle \delta F(t') \delta F(t' - y) \rangle = \langle \delta F(0) \delta F(-y) \rangle
\]

\[
= \langle \delta F(0) \delta F(y) \rangle \tag{B.14}
\]

where the last equality is due to the evenness of the correlation function. The integral in (B.13) is now substantial in the region shown in Fig. B.5, where $y = t' - t'' \approx 0$. Since the integrand is only important near $y \approx 0$, we can replace the upper limit of $y$-integration by $+\infty$ and the lower limit of $y$-integration by $-\infty$. Then (B.13) becomes

\[
I = e^{-2\nu t} \int_0^t dt' e^{2\nu t'} \int_{-\infty}^{\infty} dy \ \langle \delta F(0) \delta F(y) \rangle \tag{B.15}
\]

where we have discarded the factor $e^{-\nu y}$ that is unity when $y \approx 0$ where the integrand is important. The $t'$ integration can now be performed,

\[
I = \frac{1}{2\nu} (1 - e^{-2\nu t}) \int_{-\infty}^{\infty} dy \ \langle \delta F(0) \delta F(y) \rangle \tag{B.16}
\]

so that the full equation (B.11) now reads

\[
\langle v^2(t) \rangle = v_0^2 e^{-2\nu t} + \frac{1}{2\nu} (1 - e^{-2\nu t}) \int_{-\infty}^{\infty} dy \ \langle \delta F(0) \delta F(y) \rangle \tag{B.17}
\]

If we allow the time to become very large compared to the dissipation time $\nu^{-1}$, then we obtain an expression for the thermal fluctuations of $v^2$,

\[
\langle v^2(t) \rangle \xrightarrow{t \to \infty} \frac{1}{2\nu} \int_{-\infty}^{\infty} dy \ \langle \delta F(0) \delta F(y) \rangle \tag{B.18}
\]

However, we know from elementary thermodynamics that in thermal equilibrium, the Brownian particle will have $\frac{1}{2} T$ of kinetic energy per degree of freedom (Boltzmann's constant is as usual absorbed into the temperature $T$). Thus, elementary thermodynamics predicts

\[
\frac{1}{2} m \langle v^2(t) \rangle = \frac{1}{2} T \tag{B.19}
\]
or
\[ \langle v^2(t) \rangle = \frac{T}{M} \] (B.20)

Equating (B.18) and (B.20) we have
\[ \frac{T}{M} = \frac{1}{2\nu} \int_{-\infty}^{\infty} dy \langle \delta F(0) \delta F(y) \rangle \] (B.21)
or
\[ \nu = \frac{M}{2T} \int_{-\infty}^{\infty} dy \langle \delta F(0) \delta F(y) \rangle \] (B.22)

which is the fluctuation–dissipation theorem.

Equation (B.22) expresses the amazing fact that the dissipation of a Brownian particle is directly related to the correlation function \( \langle \delta F(0) \delta F(y) \rangle \) of the fluctuating force \( F(t) = \langle F(t) \rangle + \delta F(t) \) whose ensemble average \( \langle F(t) \rangle \) produces the dissipation. This is a fundamental result of physics that applies in many situations; in the theory of electric circuits it is known as Nyquist's theorem.

This concludes our discussion of the Langevin equation and the fluctuation–dissipation theorem. In the next section, we shall consider the related topic of Markov processes and derive the Fokker–Planck equation.

### B.2 MARKOV PROCESSES AND FOKKER–PLANCK EQUATION

In the previous section, we considered the behavior of a Brownian particle and derived the Langevin equation together with a fluctuation–dissipation theorem. In this section, we show how the behavior of a Brownian particle can be described by a Fokker–Planck equation. The Fokker–Planck equation is a very general equation in physics; it describes not only Brownian particles, but any phenomenon that in some approximate sense can be thought of as a Markov process.

A Markov process is one whose value at the next measuring time depends only on its value at the present measuring time, and not on any previous measuring time. Thus, if \( x(t) \) is the random process, and \( x_n \equiv x(t_n) \), with \( t_n > t_{n-1} > \ldots > t_1 > t_0 \), a Markov process has a probability density such that
\[ \rho(x_n|x_{n-1}, x_{n-2}, \ldots, x_1, x_0) = \rho(x_n|x_{n-1}) \] (B.23)

where the notation \( \rho(a|b) \) means "the probability density of \( a \) given that \( b \) was true." Thus, for a Markov process, the probability that \( x_n = 5 \) depends only on what the value of \( x_{n-1} \) was; it does not depend on what the values of \( x_{n-2}, x_{n-3}, \) etc. were.

There are both discrete and continuous Markov processes. An example of a discrete Markov process is given by flipping a coin. A trivial example comes if we give each toss a value \( x(t_n) \equiv x_n = +1 \) for a toss of "heads" and a value \( x_n = -1 \) for a toss of "tails." Then \( x \) is clearly a Markov process, since \( \rho(x_n) = \frac{1}{2}\delta(x_n - 1) + \frac{1}{2}\delta(x_n + 1) \) does not depend on \( x_{n-1} \), much less on \( x_{n-2}, x_{n-3}, \) etc.

A better example of a discrete Markov process is given by defining the random variable
Any function in nature can be drawn as a smooth curve as shown.

\[ X(t_n) \equiv X_n \equiv \sum_{i=1}^{n_i} x_i \quad (B.24) \]

where the \( x_i \) are given by the coin tosses of the previous paragraph. Now \( X \) is clearly a Markov process, whose probability density at \( t_n \) very definitely depends on the value of \( X_{n-1} \), but on no previous value.

**EXERCISE** Calculate \( \rho(X_n|X_{n-1}) \) for this example.

To give an example of a continuous Markov process is more difficult, because a continuous Markov process cannot exist in nature. To see this, consider any random function that we can draw as a smooth curve, as in Fig. B.6. Now, on the time scale shown, it appears that \( x_{n+1} \) not only depends on \( x_n \), but also on \( x_{n-1} \). That is, \( x_{n+1} \) not only depends on \( x_n \), but also on the derivative of the function \( dx(t)/dt \bigg|_{t_n} \), which can be written

\[ \left. \frac{dx(t)}{dt} \right|_{t_n} = \frac{x_n - x_{n-1}}{\Delta t} \quad (B.25) \]

Thus, this function is not a Markov process. In fact, no function that is a continuous curve and, therefore, no physical function, can be a Markov process.

This does not mean that Markov processes cannot be a good approximation to a physical process. Consider the velocity function of the Brownian particle in the previous section (Fig. B.7). We have seen that the velocity consists of a rapid fluctuation due to each molecular collision, together with a slowing down or net friction force. Thus, on the time scale of molecular collisions, the process is not Markovian. However, on the much longer time scale of many collision times, the
situation is very nearly Markovian. The Brownian particle is performing a random walk in velocity space, and soon forgets the details of its orbit near \( t = 0 \); it does, however, remember its velocity \( v_0 \) at \( t = 0 \).

Thus, we consider the process to have three time scales (Fig. B.8): the collision time \( \tau_c \), which is the autocorrelation time of the force \( \delta F(t) \) in the Langevin equation; the time \( \Delta t \) after which we may assume to good approximation that the process is Markovian; and the dissipation time \( \nu^{-1} \). We must have \( \Delta t \gg \tau_c \); we shall further assume in this section that \( \Delta t \ll \nu^{-1} \).

Let us develop some of the mathematical properties of Markov processes. This development will lead us to the Fokker–Planck equation.

Consider the probability of a sequence of values of the random function \( x(t) \). This is

\[
\rho(x_n,x_{n-1}, \ldots, x_2, x_1, x_0) \equiv \{\text{probability that, at time } t_0, \text{ the process } x(t) \text{ has the value } x_0 \text{ and at time } t_1, x(t) \text{ has the value } x_1, \text{ and } \ldots \text{ and at time } t_n, x(t) \text{ has the value } x_n \} \text{ where } t_n > t_{n-1} > t_{n-2} \ldots > t_1 > t_0
\]

(B.26)

By the definition (B.23) we can write

\[
\rho(x_n,x_{n-1}, \ldots, x_0) = \rho(x_n|x_{n-1},x_{n-2}, \ldots, x_0) \times \rho(x_{n-1},x_{n-2}, \ldots, x_0) \Rightarrow \rho(x_n|x_{n-1})\rho(x_{n-1},x_{n-2}, \ldots, x_0) \quad (B.27)
\]

The same procedure can now be applied to the last factor on the right of (B.27), so that

\[
\rho(x_{n-1},x_{n-2}, \ldots, x_0) = \rho(x_{n-1}|x_{n-2})\rho(x_{n-2}, \ldots, x_0)
\]

(B.28)

and so on until we have finally, for a Markov process,

*Fig. B.8 Three time scales of Brownian motion.*
\[
\rho(x_n, x_{n-1}, x_{n-2}, \ldots, x_0) = \rho(x_n|x_{n-1})\rho(x_{n-1}|x_{n-2}) \ldots \rho(x_2|x_1)\rho(x_1|x_0) \rho(x_0) \tag{B.29}
\]

By elementary considerations it must also be true that
\[
o(x_n, x_{n-1}, x_{n-2}, \ldots, x_1, x_0) = \rho(x_n, x_{n-1}, \ldots, x_1|x_0)\rho(x_0) \tag{B.30}
\]
Comparing (B.30) and (B.29) we find
\[
\rho(x_n, x_{n-1}, \ldots, x_1|x_0) = \rho(x_n|x_{n-1})\rho(x_{n-1}|x_{n-2}) \ldots \rho(x_1|x_0) \tag{B.31}
\]
In particular, we can choose \( n = 2 \) to obtain
\[
\rho(x_2, x_1|x_0) = \rho(x_2|x_1)\rho(x_1|x_0) \tag{B.32}
\]
Let us now integrate this expression over all possible \( x_1 \) to obtain
\[
\rho(x_2|x_0) = \int dx_1 \rho(x_2, x_1|x_0) \tag{B.33}
\]
or
\[
\rho(x_2|x_0) = \int dx_1 \rho(x_2|x_1)\rho(x_1|x_0) \tag{B.34}
\]
which is the Chapman–Kolmogorov equation, or Smoluchovsky equation [8].
Suppose we identify \( x_1 \) with time \( t \) and \( x_2 \) as \( x(t + \Delta t) \). Suppose we further assume that
\[
\rho(x_0) \equiv \rho(x, t = t_0) = \delta(x - x_0) \tag{B.35}
\]
Then we can drop the references to \( x_0 \) in (B.34), and write
\[
\rho(x_2|x_0) = \rho(x, t + \Delta t) \tag{B.36}
\]
that is, \( x_2 \) is now denoted by \( x \), and
\[
\rho(x_1|x_0) = \rho(x_1, t) \tag{B.37}
\]
We can also change the notation of \( \rho(x_2|x_1) \); with the definition
\[
\Delta x \equiv x - x_1 \tag{B.38}
\]
we can write
\[
\rho(x_2|x_1) = \rho(x, t + \Delta t|x - \Delta x, t)
= \psi(\Delta x, t + \Delta t|x - \Delta x, t) \tag{B.39}
\]
where the transition probability \( \psi \) is defined by (B.39); \( \psi \) gives the probability that at time \( t + \Delta t \), the random process has made a jump of \( \Delta x \) from its previous value \( x - \Delta x \) at time \( t \).
With these notational changes, we can rewrite (B.34) as
\[
\rho(x, t + \Delta t) = \int d(\Delta x)\psi(\Delta x, t + \Delta t|x - \Delta x, t)\rho(x - \Delta x, t) \tag{B.40}
\]
The value $x$ appears on the right of (B.40) only in the combination $x - \Delta x$. Thus, if we assume that all of the important physics happens for small $\Delta x$, then we can make a Taylor series expansion on the right of (B.40), obtaining

$$
\rho(x, t + \Delta t) = \int d(\Delta x) \sum_{l=0}^{\infty} \left( \frac{(-\Delta x)^l}{l!} \right) \left[ \frac{\partial^l}{\partial x^l} \left[ \psi(\Delta x, t + \Delta t| x - \Delta x, t) \rho(x - \Delta x, t) \right]_{x - \Delta x = x} \right] 
$$

or

$$
\rho(x, t + \Delta t) = \int d(\Delta x) \sum_{l=0}^{\infty} \left( \frac{(-\Delta x)^l}{l!} \right) \frac{\partial^l}{\partial x^l} \left[ \psi(\Delta x, t + \Delta t|x, t) \rho(x, t) \right] 
$$

(B.41)

If the infinite sum converges, and if we can interchange the summation and integration, then we can write

$$
\rho(x, t + \Delta t) = \sum_{l=0}^{\infty} \left( \frac{(-1)^l}{l!} \right) \frac{\partial^l}{\partial x^l} \left[ \rho(x, t) \int d(\Delta x)(\Delta x)^l \psi(\Delta x, t + \Delta t|x, t) \right] 
$$

(B.42)

The quantity given by the $\Delta x$ integration is just the expectation value or ensemble average of $(\Delta x)^l$,

$$
\langle (\Delta x)^l \rangle \equiv \int d(\Delta x)(\Delta x)^l \psi(\Delta x, t + \Delta t|x, t) 
$$

(B.43)

which is itself a function of $x, t$ through $\psi$. Equation (B.42) becomes

$$
\rho(x, t + \Delta t) = \sum_{l=0}^{\infty} \left( \frac{(-1)^l}{l!} \right) \frac{\partial^l}{\partial x^l} \left[ \rho(x, t)\langle (\Delta x)^l \rangle(x, t) \right] 
$$

(B.44)

Moving the $l = 0$ term to the left side, and dividing by $\Delta t$, we have

$$
\frac{\rho(x, t + \Delta t) - \rho(x, t)}{\Delta t} = \sum_{l=1}^{\infty} \left( \frac{(-1)^l}{l!} \right) \frac{\partial^l}{\partial x^l} \left[ \rho(x, t)\langle (\Delta x)^l \rangle(x, t) \right] 
$$

(B.45)

We next take the limit as $\Delta t \to 0$. This means that we let $\Delta t$ become very small, much smaller than any macroscopic time scale (e.g., $\nu^{-1}$). However, $\Delta t$ cannot really go to zero, because this development has assumed that $\Delta t$ is large enough to justify the Markovian assumption. Thus, the left side of (B.45) becomes

$$
\lim_{\Delta t \to 0} \frac{\rho(x, t + \Delta t) - \rho(x, t)}{\Delta t} = \frac{\partial \rho(x, t)}{\partial t} 
$$

(B.46)

where the time derivative refers to macroscopic time. Equation (B.45) becomes
\[ \frac{\partial \rho}{\partial t} = \sum_{l=1}^{\infty} (-1)^l \frac{\partial^l}{\partial x^l} \left[ \lim_{\Delta t \rightarrow 0^+} \frac{\langle (\Delta x)^l \rangle}{l!\Delta t} \rho(x,t) \right] \] (B.47)

Defining the diffusion coefficients
\[ D^{(l)}(x,t) \equiv \lim_{\Delta t \rightarrow 0^+} \frac{\langle (\Delta x)^l \rangle}{l!\Delta t} \] (B.48)

Equation (B.47) is
\[ \frac{\partial \rho(x,t)}{\partial t} = \sum_{l=1}^{\infty} (-1)^l \frac{\partial^l}{\partial x^l} [D^{(l)}(x,t)\rho(x,t)] \] (B.49)

If we keep only the first two terms on the right of (B.49), we have
\[ \frac{\partial \rho(x,t)}{\partial t} = -\frac{\partial}{\partial x} [D^{(1)}(x,t)\rho(x,t)] + \frac{\partial^2}{\partial x^2} [D^{(2)}(x,t)\rho(x,t)] \] (B.50)

which is the well-known Fokker–Planck equation [9].

For Brownian motion, the random variable \( x \) is replaced by the particle velocity \( v(t) \). We shall leave it as an exercise to determine the diffusion coefficients \( D^{(1)}(v,t) \) and \( D^{(2)}(v,t) \).

**EXERCISE** Use the results of the previous section to evaluate the coefficients in Eq. (B.50) for Brownian motion. Show that \( D^{(1)}(v,t) = -\nu v \), and \( D^{(2)}(v,t) = \nu T/M \), so that the Fokker–Planck equation associated with the Langevin equation of Brownian motion is
\[ \frac{\partial \rho(v,t)}{\partial t} = -\nu \frac{\partial}{\partial v} (v\rho) + \frac{\nu T}{M} \frac{\partial^2}{\partial v^2} \rho \] (B.51)

**EXERCISE** Use the results of the previous section to show that \( D^{(3)}(v,t) \sim \Delta t \) and, thus, vanishes as \( \Delta t \to 0^+ \).

We can now understand why we are able to write the Lenard–Balescu equation in the form of a Fokker–Planck equation,
\[ \frac{\partial f(v_1,t)}{\partial t} = -\nabla_{v_1} \cdot (Af) + \frac{1}{2} \nabla_{v_1} \nabla_{v_2} : \langle \hat{B} f \rangle \] (B.52)

Because the derivation of Lenard–Balescu assumed \( g(1,2) \ll f_1(1)f_1(2) \), we have effectively limited ourselves to small angle two-body collisions. The quantity \( f(v_1,t) \) may be thought of as the probability density of particles in velocity space. Thus, \( f(v_1,t) \) is changing slowly on the time scale for a two-body collision. All of these features are precisely those assumed in the derivation of the Fokker–Planck equation. It should come as no surprise to us that the Lenard–Balescu equation can be written in the form of the Fokker–Planck equation. The coefficient \( A \) in (B.52) is called the coefficient of dynamic friction, and plays the same role as \( \nu v \) in the Fokker–Planck equation (B.51) for Brownian motion. It represents the slowing
down of a particle due to many small angle Coulomb collisions. Likewise, the coefficient \( \bar{B} \) in (B.52) is called the diffusion coefficient, and plays the same role as \( \nu T/M \) in (B.51). It represents the diffusion of the plasma particles in velocity space due to many small angle collisions.

In the steady state, a typical particle is suffering dynamic friction plus diffusion; the net effect is to produce a Maxwellian. This is just as true in a plasma as it is for a Brownian particle.

In addition to the stated references, sources for this appendix include the book by Stratonovich [10] and the ageless and excellent article by Chandrasekhar [11].

REFERENCES

Many parts of this book make use of the basic results of the theory of complex variables [1, 2]. For the benefit of readers who have not yet studied this subject in detail, or who have studied it long enough ago to have forgotten it, these basic results are summarized here.

The most useful result is the *residue theorem*, which states that the integral in a counterclockwise direction around a closed curve is \(2\pi i\) times the sum of the residues. If the integrand is of the form \(f(z)(z - z_0)^{-1}\), the residue at the *simple pole* \(z = z_0\) is \(f(z_0)\). For example, consider the integral

\[
I = \int_{-\infty}^{\infty} \frac{dz}{z^2 + a^2}
\]

where the integration is along the real \(z\)-axis, and \(a > 0\). The integration can be closed by a large semicircle at infinity, since the contribution from the semicircle is

\[
\sim \lim_{R \to \infty} \left( \frac{\pi R}{R^2} \right) = \lim_{R \to \infty} \left( \frac{\pi}{R} \right) = 0
\]

The semicircle can occur in either the upper-half \(z\)-plane or the lower-half \(z\)-plane (Fig. C.1). Writing (C.1) as

\[
I = \oint \frac{dz}{(z + ia)(z - ia)}
\]

we close the contour downward, changing the sign on the result because this is in the clockwise direction, to obtain (only the pole at \(z = -ia\) is enclosed)

\[
I = (-2\pi i) \left. \frac{1}{z - ia} \right|_{z = -ia} = \frac{\pi}{a}
\]

(C.3)
**EXERCISE**  Obtain the same result by closing upward.

The solution of many ordinary and partial differential equations is facilitated by *Fourier and Laplace transformation*. The Fourier transform conventions used in this book, stated in Chapter 5, are for functions of one spatial dimension \( x \),

\[
f(k) = \int_{-\infty}^{\infty} \frac{dx}{2\pi} f(x) \exp(-ikx)
\]  \hspace{1cm} (C.4)

with inverse transform

\[
f(x) = \int_{-\infty}^{\infty} dk \ f(k) \exp(ikx)
\]  \hspace{1cm} (C.5)

The \( x \) and \( k \) integrations are along the real axes. The Laplace transform conventions for functions of time \( t \) are

\[
f(\omega) = \int_{0}^{\infty} dt \ f(t) \exp(i\omega t)
\]  \hspace{1cm} (C.6)

with inverse transform

\[
f(t) = \int_{L} \frac{d\omega}{2\pi} f(\omega) \exp(-i\omega t)
\]  \hspace{1cm} (C.7)

where the Laplace contour \( L \) is a horizontal line in the complex \( \omega \)-plane that must pass above all singularities of \( f(\omega) \). The Laplace transform (C.6) can be considered as the Fourier transform of the function \( \tilde{f}(t) \) such that \( \tilde{f}(t) = f(t) \) for \( t > 0 \) and \( \tilde{f}(t) = 0 \) for \( t < 0 \). Then for \( t < 0 \) the inverse Laplace transform (C.7) can be closed upward [since \( \exp(-i\omega t) \sim \exp(-|t|\omega) \rightarrow 0 \) for \( \omega \rightarrow +\infty \)], yielding \( \tilde{f}(t) = 0 \) for \( t < 0 \) since the Laplace contour passes above all singularities of \( f(\omega) \).

Consider the solution of the differential equation

\[
\frac{df}{dt} = \alpha f
\]  \hspace{1cm} (C.8)
with \( f(t = 0) = f_0 \). The Laplace transform of the left side is

\[
\int_0^\infty dt \frac{df(t)}{dt} \exp(i\omega t) = f(t) \exp(i\omega t)\bigg|_0^\infty
\]

\[
- i\omega \int_0^\infty dt f(t) \exp(i\omega t) = f(t) \exp(i\omega t)\bigg|_0^\infty - i\omega f(\omega)
\]

(C.9)

Without knowing the function \( f(t) \), we can only say that this integral is defined for \( \omega \) large enough, for only then is \( f(t) \exp(i\omega t)\big|_{i\omega \to \infty} \) equal to zero. How large is large enough remains to be seen. For large enough \( \omega \), Eq. (C.8) has the Laplace transform

\[
- f(t = 0) - i\omega f(\omega) = \alpha f(\omega)
\]

(C.10)

so that

\[
f(\omega) = \frac{i f(t = 0)}{\omega - i\alpha}
\]

(C.11)

The inverse transform is

\[
f(t) = \int_L \frac{d\omega}{2\pi} \frac{i f(t = 0)}{\omega - i\alpha} \exp(-i\omega t)
\]

(C.12)

where the contour must be placed high enough in the \( \omega \)-plane so that \( f(\omega) \) is defined (the shaded region in Fig. C.2). Once the contour is drawn in the shaded region of Fig. C.2, it can be moved around only if \( f(\omega) \) is analytically continued to the remainder of the complex \( \omega \)-plane. An analytic function is one that is differentiable (the derivative in the complex plane at the point \( z \) does not depend on which direction the point is approached from). The analytic continuation of a simple function like \( f(\omega) \) in (C.11) from the shaded region in Fig. C.2 [the only region where (C.10) is defined] to the entire \( \omega \)-plane is easy; it is just the function

\[
f(\omega) = \frac{i f(t = 0)}{\omega - i\alpha}
\]

(C.13)

---

Fig. C.2 Inverse Laplace contour must be drawn initially high in the \( \omega \)-plane.
itself. This function is now analytic in the entire \( \omega \)-plane except at the point \( \omega = ia \). The contour in (C.12) can now be closed by a large semicircle in the lower-half \( \omega \)-plane, since \( f(\omega) \) is defined everywhere. The result is

\[
f(t) = -\frac{2\pi i(t)}{2\pi} f(t = 0) \exp(\alpha t) = f(t = 0) \exp(\alpha t)
\]

which is the desired result. In retrospect, we can now see that (C.9) converges for \( \omega_i > \alpha \). This is why the inverse Laplace contour must be drawn above all singularities of \( f(\omega) \) in the \( \omega \)-plane.

**Analytic continuation** is not always quite as simple as in (C.13). Consider

\[
f(z) = \int_{-\infty}^{\infty} \frac{dx}{(x^2 + a^2)(x - z)}
\]

defined for \( z_i > 0 \) with \( a > 0 \); the integration is along the real \( x \)-axis. Closing the contour either up or down (Fig. C.3), we find

\[
f(z) = \frac{-\pi}{a} \frac{1}{z + ia}
\]

for \( z_i > 0 \). We cannot use (C.15) as the analytic continuation of \( f(z) \) for \( z_i < 0 \), for then (C.15) yields

\[
f(z) = \frac{-\pi}{a} \frac{1}{z + ia} - \frac{2\pi i}{z^2 + a^2}
\]

for \( z_i < 0 \). The function \( f(z) \) defined by (C.16) and (C.17) is discontinuous at \( z_i = 0 \) and so is not analytic. In order to properly analytically continue (C.15), one must subtract the extra term in (C.17) that leads to the discontinuity, and write

\[
f(z) = \int_{-\infty}^{\infty} \frac{dx}{(x^2 + a^2)(x - z)} + \frac{2\pi i}{z^2 + a^2}
\]

\[\text{Fig. C.3} \quad \text{Evaluation of } f(z) \text{ for } z_i > 0 \text{ in (C.15).}\]
for \(z_i < 0\). The combination (C.15) for \(z_i > 0\) and (C.18) for \(z_i < 0\) is now an analytic function everywhere except at the pole of (C.16), \(z = -ia\). Alternatively, one can deform the contour in (C.15) as shown in Fig. C.4 for \(z_i < 0\), and write

\[
f(z) = \int_{c'} \frac{dx}{(x^2 + a^2)(x - z)}
\]

(C.19)

The contour \(c'\) is as shown in Fig. C.4 for \(z_i < 0\), and is along the real \(x\)-axis for \(z_i > 0\). This gives the same result as the form (C.18) for \(z_i < 0\).

A useful formula for Fourier transformation is

\[
\int_{-\infty}^{\infty} \frac{dx}{2\pi} \exp(-ikx) = \delta(k)
\]

(C.20)

This formula can be demonstrated by multiplying each side by an arbitrary function \(f(k)\) and integrating over all \(k\). The right side yields \(f(k = 0)\), while the left side is

\[
\int_{-\infty}^{\infty} dk f(k) \int_{-\infty}^{\infty} \frac{dx}{2\pi} \exp(-ikx) = \int_{-\infty}^{\infty} \frac{dx}{2\pi} \int_{-\infty}^{\infty} dk f(k) \exp(-ikx)
\]

\[
= \int_{-\infty}^{\infty} \frac{dx}{2\pi} f(x)
\]

\[
= f(k = 0)
\]

(C.21)

where it has been assumed that the order of integrations can be reversed. Since the right and left sides of (C.20) yield the same result, the identification (C.20) must be correct.

Another useful formula concerns integrals of the form

\[
I = \lim_{\eta \to 0} \int_{-\infty}^{\infty} dx \frac{1}{x - a \pm i|\eta|}
\]

(C.22)
where the integral is along the real $x$-axis, and $a > 0$. For the lower sign, the pole is at $x = a + i|\eta|$, and the integral can be performed by slightly deforming the contour as shown in Fig. C.5. This leads to

$$I = P \int_{-\infty}^{\infty} dx \frac{1}{x - a} + \pi i$$

(C.23)

where the semicircle in Fig. C.5 contributes half of $2\pi i$, and where

$$P \int_{-\infty}^{\infty} = \lim_{\epsilon \to 0} \left[ \int_{-\infty}^{a-\epsilon} + \int_{a+\epsilon}^{\infty} \right]$$

(C.24)

Formally, one writes

$$\lim_{\eta \to 0} \frac{1}{x - a - i|\eta|} = P \left( \frac{1}{x - a} \right) + \pi i \delta(x - a)$$

(C.25)

which when integrated over $x$ yields (C.23). For the upper sign in (C.22), the pole approaches the integration contour from below, the integration contour must be deformed upward rather than downward, and the sign of the imaginary contribution changes. The general formula is finally

$$\lim_{\eta \to 0} \frac{1}{x - a \pm i|\eta|} = P \left( \frac{1}{x - a} \right) \mp \pi i \delta(x - a)$$

(C.26)

Other properties of complex variables are explored throughout the book.

Vector and Tensor Identities

The following vector and tensor identities are useful in the study of plasma physics [1].

\[
A \cdot (B \times C) = (A \times B) \cdot C = B \cdot (C \times A) = (B \times C) \cdot A
\]

\[
= C \cdot (A \times B) = (C \times A) \cdot B
\]

\[
A \times (B \times C) = (A \cdot C)B - (A \cdot B)C
\]

\[
(A \times B) \cdot (C \times D) = (A \cdot C)(B \cdot D) - (A \cdot D)(B \cdot C)
\]

\[
\nabla(jg) = f\nabla g + g\nabla f
\]

\[
\nabla \cdot (fA) = f\nabla \cdot A + A \cdot \nabla f
\]

\[
\nabla \times (fA) = f\nabla \times A + \nabla f \times A
\]

\[
\nabla \cdot (A \times B) = B \cdot (\nabla \times A) - A \cdot (\nabla \times B)
\]

\[
\nabla \times (A \times B) = A(\nabla \cdot B) - B(\nabla \cdot A) + (B \cdot \nabla)A - (A \cdot \nabla)B
\]

\[
\nabla(A \cdot B) = A \times (\nabla \times B) + B \times (\nabla \times A) + (A \cdot \nabla)B + (B \cdot \nabla)A
\]

\[
\nabla^2 A = \nabla(\nabla \cdot A) - \nabla \times (\nabla \times A)
\]

\[
\nabla \times \nabla f = 0
\]

\[
\nabla \cdot (\nabla \times A) = 0
\]

\[
\nabla \cdot (B A) = A(\nabla \cdot B) + (B \cdot \nabla)A
\]

\[
\nabla \cdot (f \vec{T}) = (\nabla f) \cdot \vec{T} + f \nabla \cdot \vec{T}
\]
